The investigations that have been made in recent years indicate that psychiatric problems are coming rapidly to the fore as a primary cause of disability and illness. During the war institutions for the care of the mentally disturbed suffered the deterioration that was characteristic of many other medical agencies, in most instances due to lack of funds. Thus any comprehensive program for the care of public health must require the development of a program of mental hygi-

*(Continued on page 530)*

# PROGRAM OF THE AMERICAN MEDICAL ASSOCIATION FOR THE ADVANCEMENT OF MEDICINE AND PUBLIC HEALTH

---

### A Federal Department of Health

1. Creation of a Federal Department of Health of Cabinet status with a Secretary who is a Doctor of Medicine, and the coordination and integration of all Federal health activities under this Department, except for the military activities of the medical services of the armed forces.

### Medical Research

2. Promotion of medical research through a National Science Foundation with grants to private institutions which have facilities and personnel sufficient to carry on qualified research.

### Voluntary Insurance

3. Further development and wider coverage by voluntary hospital and medical care plans to meet the costs of illness, with extension as rapidly as possible into rural areas. Aid through the states to the indigent and medically indigent by the utilization of voluntary hospital and medical care plans with local administration and local determination of needs.

### Medical Care Authority with Consumer Representation

4. Establishment in each state of a medical care authority to receive and administer funds with proper representation of medical and consumer interest.

### New Facilities

5. Encouragement of prompt development of diagnostic facilities, health centers and hospital services, locally originated, for rural and other areas in which the need can be shown and with local administration and control as provided by the National Hospital Survey and Construction Act or by suitable private agencies.

### Public Health

6. Establishment of local public health units and services and incorporation in health centers and local public health units of such services as communicable disease control, vital statistics, environmental sanitation, control of venereal diseases, maternal and child hygiene and public health laboratory services. Remuneration of health officials commensurate with their responsibility.

### Mental Hygiene

7. The development of a program of mental hygiene with aid to mental hygiene clinics in suitable areas.

### Health Education

8. Health education programs administered through suitable state and local health and medical agencies to inform the people of the available facilities and of their own responsibilities in health care.

### Chronic Diseases and the Aged

9. Provision of facilities for care and rehabilitation of the aged and those with chronic disease and various other groups not covered by existing proposals.

### Veterans' Medical Care

10. Integration of veterans' medical care and hospital facilities with other medical care and hospital programs and with the maintenance of high standards of medical care, including care of the veteran in his own community by a physician of his own choice.

### Industrial Medicine

11. Greater emphasis on the program of industrial medicine, with increased safeguards against industrial hazards and prevention of accidents occurring on the highway, home and on the farm.

### Medical Education and Personnel

12. Adequate support with funds free from political control, domination and regulation of the medical, dental and nursing schools and other institutions necessary for the training of specialized personnel required in the provision and distribution of medical care.

ene and the establishment of mental hygiene clinics in suitable areas.

Experience has shown that vast numbers of people are not only unaware of the basic principles of personal and public hygiene but also unaware of easily available medical facilities in their own neighborhoods. These people can be reached only by a program of health education directed specifically to them and utilizing the mediums of information with which they would be continuously in contact. Health education should be a function not only of federal agencies but also of state and local public health agencies and of the medical profession. The philanthropic and voluntary health organizations in the United States do a far better job in relation to such conditions as cancer, tuberculosis, heart disease, infantile paralysis and other conditions than do the governmental agencies.

As far as can be determined, proposed legislation, including that for compulsory sickness insurance, would not reach the aged. Neither would it satisfactorily cover those with long-standing chronic diseases nor such underprivileged groups as the Negro population and the Indians. Certainly special legislation would be required to provide facilities for care and rehabilitation of these groups.

The Hoover Commission and other governmental agencies which have recently been concerned with the vast wastefulness that prevails in medical care under federal governmental auspices have insisted that there should be integration of veterans' medical care and hospital facilities with other medical care and hospital programs. Already the public is aware of the losses that occur from duplication of medical facilities by the Army and Navy and Public Health Service. The changes that have come about in the care of the veteran since the fundamental change in administration that began with General Bradley and has been continued under Mr. Gray have raised tremendously the standard of veterans' medical care. Among the most important aspects of this procedure have been the care of the veteran in his own community by a physician of his own choice and the utilization of the voluntary insurance plans.

More emphasis on industrial medicine and the prevention of unnecessary accidents would vastly benefit the American people. Today accidents are fourth in the list of the causes of death. A suitable program on prevention of accidents would make available, according to recent estimates, more than 10 and possibly 15 per cent of the beds now occupied in all hospitals by the victims of accidents.

Finally, a system of medical care cannot rise above the level of the medical, dental and nursing education and the accessory medical professions. Today these agencies are without adequate funds to bring about necessary improvements. A voluntary foundation is in process of development in order to secure additional funds. Conceivably the states will do more for their state medical schools than they have done in the past. Possibly also federal funds may be necessary, but whenever governmental funds are used they must be employed under some system that would make their use free from political control, domination and regulation by governmental agencies.

This program is far more comprehensive than any yet proposed by either the President of the United States or the Federal Security Administrator. It has the advantage that it can be developed and administered as a logical evolution from the existing institutions in the United States without bringing about chaos through a complete overthrow of what has already been admitted by every one to be the highest quality of medical care available in any country in the world.

## Current Comment

### A PROTEST ON AMERICAN MEDICAL ASSOCIATION POLICY AND A REPLY

Under Association News in this issue of The Journal appears a protest signed by one hundred and forty-eight physicians, which has already had publicity in the press. Apparently it was released in New York by one of the five members of the committee which forwarded it to the American Medical Association, including Drs. George Baehr, New York; E. A. Park, Baltimore; Hugh Morgan, Nashville; Barry Wood, St. Louis, and Walter Bauer, Boston. The protest, as will be observed by physicians who can remember a similar previous incident, resembles the action taken by a so-called Committee of 400 who attempted to state their views against the policies of the House of Delegates of the American Medical Association. The present incident is particularly dismaying because it comes at a time when the medical profession of the United States, as represented by the American Medical Association, is in a critical struggle against the forces that would introduce nationalization of medicine into the United States. The experience of Great Britain indicates that the medical profession there, as represented by the British Medical Association, might have accomplished far more had they not been subjected to separate negotiations carried on by specialistic groups and others who wished for some reason to stand apart from the great majority of the medical profession. The Board of Trustees of the American Medical Association invited the committee to come before the full Board to present their point of view. This they did, the one hundred and forty-eight being represented by Drs. Hugh Morgan, E. A. Park, Barry Wood and Henry F. Helmholz. The Board itself was represented in the considerations by Dr. R. L. Sensenich, President of the Association, Dr. Elmer L. Henderson, Chairman of the Board, and Dr. Louis H. Bauer, Chairman of the Executive Committee of the Board. Notwithstanding presentation to this group of the program of the Association (which appears elsewhere in this issue), notwithstanding information given to them as to the progress that is being made toward the development of nationally functioning voluntary hospital and sickness insurance and notwithstanding many other important facts that they probably should have known, they persisted in their request that the protest with the one hundred and forty-eight names be printed. Fortunately the people of the United States are being steadily and continually enlightened by the educational program of the American Medical Association on the various aspects of the problems concerned in providing medical care. The action taken by the one hundred and forty-eight protesters will apparently have little if any influence on the ultimate results.

## LETTERHEADS EMPHASIZE TREND TO CENTRALIZED GOVERNMENT

Medical and public health agencies used to receive letters from the United States Public Health Service, a highly regarded agency of the federal government. This agency began as the Marine Hospital Service in the Treasury Department and for many years remained there, functioning as a professional agency with nominal responsibility to the Secretary of the Treasury but virtual self determination in professional matters. In like manner the United States Office of Education functioned in the Department of the Interior; its letterheads bore the title "United States Office of Education." A federal reorganization removed both these agencies from the departments in which they had previously been administered into a new welfare consolidation, the Federal Security Agency. Now the "U. S." portion of the title has disappeared from the letterheads of both the Public Health Service and the Office of Education. The titles of these agencies are in small type under the over-all aegis of the Federal Security Agency, which name looms large at the top of the letterhead. What significance should be attached to the metamorphosis of the letterheads of two professional agencies vitally concerned with public health and welfare? The Federal Security Administrator, Mr. Oscar Ewing, has been assuring the medical profession that it has nothing to fear from his plans for federalizing medical care. What appears to be happening to the professional services under the Administrator's authority is not reassuring!

## ENDOGENOUS PHTHISIS

In recent years superinfection in tuberculosis has been emphasized more and more by the epidemiologist. An endogenous development, however, is still defensible on clinical evidence as well as that supplied by morbid anatomy. While the question can hardly be decided, both superinfection and an endogenous development must be regarded as possible. The description of clearcut observations demonstrating the origin of the early foci is still necessary. Woolf[1] uses the term "endogenous development" not in the restricted sense of blood-borne spread from a recrudescent primary focus but more broadly to include those cases in which a primary or postprimary focus, following a protracted course involving several alternating periods of exacerbation and regression, constitutes a source for bronchogenic spread. The final recrudescence is often precipitated by an intervening nontuberculous disease. In this light, Woolf presents 4 cases with one feature in common: viz., the morbid anatomic evidence of local recrudescence—namely (*a*) the coexistence of calcified spots with liquefied areas and (*b*) the collection of enormous numbers of tubercle bacilli in the circumscribed foci in which liquefaction is beginning. Bacillary multiplication was demonstrable as the leading event in liquefaction. According to Woolf, local recrudescence of an old focus is a well defined entity in the development of phthisis. For this question of the actual origin of the focus, whether exogenous or hematogenous, primary or postprimary, does not appear to be as decisive as the fact of its longstanding presence and final breakdown. This constitutes the evidence of an endogenous development of phthisis in these cases; the further bronchogenic spread which will cause phthisis does not emanate from an outside source but from a lesion already present in the body for a long time. Endogenous development seems to constitute a definite source of phthisis. The part of malnutrition, exposure and diabetes in precipitating recrudescence appears to be demonstrated also.

## BLOOD SUGAR AND ACCLIMATIZATION

As might be expected from the reduction in partial pressure of oxygen, the most pronounced changes in the organism in response to high altitude are seen in the respiratory and circulatory systems. An increase in pulmonary total ventilation, a rise in concentration of hemoglobin in the blood and an increase in the number of red blood corpuscles in the systemic circulation ensue. That other far reaching disturbances may be expected from the anoxia induced by the reduction of barometric pressure is indicated by recent studies[1] of blood sugar changes in acclimatization to altitude. The normal response to low pressure is an increase in blood sugar. Subsequent more or less chronic anoxia failed to elicit such an increase which indicated that the mechanism involved in producing the hyperglycemia showed the effect of acclimatization. When the exposure to low pressure ceased most of the experimental animals (dogs) reverted to normal with respect to response of blood sugar to anoxia; in one, however, acclimatization persisted more than two months and in another, seven months. The precise mechanism of this phenomenon needs further study.

# ORGANIZATION SECTION

## Official Notes

### A PROTEST AGAINST THE PRESENT ATTITUDES AND POLICIES OF THE A. M. A. IN REGARD TO THE PROBLEM OF MEDICAL CARE

Numerous comments by medical colleagues in various parts of of the country have convinced the undersigned physicians that a large segment of the medical profession is not in sympathy with many policies and actions of the American Medical Association on the extension of medical care. The $25 assessment levied in executive session on all members of the Association will place several million dollars at the disposal of its officials. Only an indefinite and constructively inadequate program has been presented outlining the way in which this huge fund will be used. The charge to Association officials is exceedingly vague, leaving the methods to be employed at their discretion and subject to the possibility of grave abuse.

If the funds are to be used for propaganda and legislative lobbying instead of developing a comprehensive medical care program, we are heartily opposed to the levy and shall refuse to pay it, and we urge all physicians with a sense of responsibility for the future of American medicine to register their protest. The significance of standpat propaganda will not escape the public. This will add to the already firmly rooted suspicion that the Association's objectives are primarily economic and selfish and will further weaken its standing as an altruistic agency devoted to the improvement of medical practice, research and education. We would gladly contribute if the funds were to be used to develop a carefully worked out, comprehensive plan to extend and improve medical care and education.

We believe that the fundamental failure of the American Medical Association in its attitudes and policies bearing on the general problem of medical care has been its unwillingness fully to acknowledge the need for improvement and to seize this particularly favorable opportunity to come forward with a comprehensive, constructive program which would be of clear advantage to the public as well as to the profession itself. Further, we believe that in the present crisis the obvious direct way to avoid an all-inclusive compulsory health insurance and to make secure the valuable features of our present system is for the Association to develop a program that will be manifestly so considerate of the needs of the people and at the same time so eminently fair to the interests of the physicians that it will command general approbation.

The undersigned believe that now is the time to voice our disapproval of the leadership and policies of the Association on the extension of medical care.

### REPLY BY OFFICERS AND TRUSTEES

The preceding statement of protest requires an official reply by the Board of Trustees, since it is essentially a criticism of policies adopted by the House of Delegates, the representative body of the American Medical Association. The protest voices moreover distrust of the competence of the Board to administer the funds developed by the special assessment and emphasizes disapproval by the signers of the leadership and policies of the Association related to the extension of medical care.

Before analyzing the protest, the Board of Trustees calls attention to the fact that not one of the signers of the protest attempted, through direct inquiry to the headaquarters or to any official of the Association to determine:

1. Whether or not the American Medical Association has a program for the extension of medical care.
2. Whether or not measures were in effect to promote the activation of such a program.
3. The activities related to determining existing unmet needs for medical care.
4. The relationships established by the Association with organizations representing the farmer, labor, education, welfare and similar groups.

The first sentence of the protest intimates that "a large segment of the medical profession is not in sympathy," etc. Actual surveys indicate that at least 85 per cent of the medical profession is in sympathy and is voluntarily contributing the assessment.

The remaining sentences of the first paragraph express doubt as to the manner in which the Board of Trustees will administer the funds arising from the special assessment. The Board of Trustees, under the Constitution of the Association, is charged with full responsibility for all funds and property of the Association. The assets of the Association are in excess of $10,000,000 and the annual expenditures in excess of $4,000,000. The assessment funds will be spent according to plans already made and for which budgets have been approved. The statement has already been published and is here reaffirmed that this fund is not for lobbying nor in any way a "slush" fund, but that it will be devoted chiefly to education of the American people as to the present high quality of medical service in our country, as to the inevitable deterioration, as shown in other countries associated with a governmental system of medical care and also to accelerate in every way possible the enrolment of the people in voluntary hospitalization and medical care plans. This is the first time, since the Association developed into an important, financially significant organization, that any doubt has even been hinted as to the dependability of the Board of Trustees in administering the funds.

The second paragraph of the protest begins with an "if" clause; the signers could have learned on suitable inquiry before signing that the funds are not being used for "legislative lobbying." If education and information of the public relative to medical care in the United States are "propaganda" the signers should understand that such education is a significant part of the Association's program. The protest mentions an "already firmly rooted suspicion that the Association's objectives are primarily economic and selfish"; the allegation is made without specifying the extent of this suspicion or the names of those in whom it is "firmly rooted." Can it be that the signers of the protest are thus "firmly rooted" in their views? When the four representatives of the signers met with the Board of Trustees they were given full information as to the "comprehensive plan to extend and improve medical care and education." Whether or not they considered it "carefully worked out" and sufficient did not become apparent. They did continue to insist that their protest be published, notwithstanding their admission of unfamiliarity with the details of the Association's activities and its program.

The third paragraph of the protest alleges that the Association has been unwilling to "acknowledge the need for improvement." This statement is without any support by actual evidence. The "comprehensive, constructive program" of the Association printed in this issue of The Journal is proof to the contrary. This program is an extension and a broadening of previous programs, many phases of which have already been implemented.

In the original communication received from this group, the final paragraph read "The undersigned believe that now is the time to voice our disapproval of the leadership and policies of the Association." About a week later an additional clause was added indicating that this disapproval was limited exclusively to "the extension of medical care." When the four representatives conferred with the Board of Trustees they admitted that the phrase had been added and the sentence modified without notifying the original signers of the protest.

The Board of Trustees is convinced that the circulation and issuance of this protest is an unfortunate disservice to the cause of the medical profession of the United States. It is not based on knowledge or fact as to the policies or activities of the American Medical Association.

Signed:

Roscoe L. Senenich, President
R. W. Fouts, Vice President
Ernest E. Irons, President-Elect
Josiah J. Moore, Treasurer
F. F. Borzell, Speaker of the House of Delegates
George F. Lull, Secretary and General Manager
Morris Fishbein, Editor

Board of Trustees:

## THE JUDICIAL COUNCIL COMMENTS ON REBATES

In the issue of The Journal of the American Medical Association, Oct. 30, 1948, page 650, under the heading "Council on Physical Medicine, Rebates," the following pronouncement is made: "When he, himself (the physician) furnishes drugs, spectacles or any physical appliance and when he is able to service such physical appliances, he is entitled to a fair profit on these articles of merchandise in addition to and above his own professional fee and such a profit on such articles of merchandise does not in any way constitute a rebate or 'kick-back.'"

That statement expressing an opinion which is entirely contrary to the Principles of Medical Ethics will doubtless cause confusion in the minds of many physicians and may be responsible for violation of the accepted Principles of Medical Ethics.

There has been no change made in the Principles of Medical Ethics. This statement is now printed in order that Chapter I, Section 6 may not be unwittingly violated. The statement reflects an action taken by the Judicial Council in St. Louis on Dec. 2, 1948.

Judicial Council.
E. R. Cunniffe, Chairman.
Louis A. Buie.
Walter F. Donaldson.
H. L. Pearson Jr.
George F. Lull, Secretary.

## Washington Letter

*(From a Special Correspondent)*

Feb. 14, 1949.

### Immigration of 500 Displaced Physicians Sought

A bill (H. R. 2018) introduced in the House by Representative Case (South Dakota) has as its purpose the amendment of the Displaced Persons Act to permit admission into the United States of 500 displaced doctors and 1,000 nurses for employment in government hospitals. Modification of the displaced persons law to rectify a number of inequities is almost certain to be accomplished this year, and the Case plan probably will be considered by the House Judiciary Committee in conjunction with other proposed amendments.

### Hawley Critique Made Public by Senator Lodge

Signs that Senator Henry Cabot Lodge Jr., Republican, of Massachusetts, will aline himself with members of Congress prepared to vote against compulsory sickness insurance were seen in his issuance, on January 31, of a letter which he had received from Dr. Paul R. Hawley. The letter has been printed in the *Congressional Record* of that date. It says that the executive committee for the National Health Assembly, held in Washington last May under Federal Security Agency auspices, served more as "window dressing" than as an executive body with a working role; that the names of its members were used by Administrator Oscar R. Ewing in a manner that bordered on "sharp practice" and that the fact that the ten year health plan subsequently issued by Ewing did not necessarily coincide with views of the National Health Assembly was not made sufficiently conspicuous in the Ewing report.

"I am firmly convinced," wrote Dr. Hawley, chief executive officer of the Blue Cross and Blue Shield Commissions, "that compulsory health insurance will inevitably lower the quality of medical practice in this country. This will be a thousand times worse for our people than a distribution of medical care which may not be all that we want it to be. I think it far more important that 80 per cent of our people obtain medical care of the highest quality than that 100 per cent get only low quality medical care. . . . Compulsory health insurance will force a lowering of quality that can never again be raised."

### Farm Bureau Federation Protests S. 5 Bill

The Senate Committee on Labor and Public Welfare has received from the American Farm Bureau Federation a strong protest against enactment of compulsory sickness insurance. Representing a membership of 1,325,000 farm families, the federation urged the committee, to which the new Murray-Wagner-Dingell bill (S. 5) has been referred, to refrain from reporting the measure to the Senate floor before opponents receive a full hearing.

"We strongly oppose plans under which the Federal government would embark on programs providing similar services on a compulsory basis," said the federation, with reference to medical care now being performed by voluntary organizations. "We have consistently opposed compulsory health insurance. We favor voluntary programs providing hospital and medical care, facilities to train more doctors and nurses, establishment of local public health units and a broad program of health education."

Presently devoting practically all its time to the task of amending labor legislation, the Senate Committee on Labor and Public Welfare is not expected to schedule public hearings on national health legislation before the latter part of March.

### Federal Arthritis Legislation Introduced

A concerted drive to have Congress enact special legislation to stimulate research, training and other factors in arthritis and rheumatic diseases was launched late in January. Bills that would do in this field what the federal government already has done in cancer, heart disease, mental hygiene and dental research were introduced simultaneously in House and Senate by Representatives Priest, Javits, Keefe and Smathers and Senators Pepper and Murray. A speech in support of the legislation was delivered on the House floor by Representative Judd, a physician. It is probable that public hearings on the bills will be held by the Senate Labor and Public Welfare Committee and the House Interstate and Foreign Commerce Committee.

# Medical Legislation

## STATE LEGISLATION

### Arizona

**Bills Introduced.**—H. 36 proposes the enactment of a complete revision of the traffic laws including the admissibility in evidence, in criminal prosecutions, of the results of chemical analyses of **the defendant's blood, urine, breath or other bodily substance** which have been made to determine whether or not the accused is under the influence of intoxicating liquor. *H. 82 proposes a complete revision and reenactment of the* medical practice act. Among some of the important changes suggested are the right to make use of the injunctive process in enforcing violations of the act and the declaration that **the giving or receiving of rebates** shall be construed to be within the meaning of unprofessional conduct. S. 40 proposes to require **applicants for a marriage license** to present a certificate of a duly licensed physician stating that the applicant has been given an examination for syphilis and other venereal diseases and that the applicant does not have such disease in a communicable stage.

### Arkansas

**Bills Introduced.**—H. 225, to amend the basic science act, proposes **to exempt chiropractors** therefrom. S. 75 proposes to require all **applicants for a marriage license** to file a medical certificate from a duly licensed physician which certificate shall state that the applicant has been *given such physical examination as may be necessary for the* discovery of syphilis and that in the opinion of such physician the person is not infected with syphilis in a stage which is or may become communicable to the marital partner.

### Georgia

**Bills Introduced.**—S. 77 proposes the creation of a state **board of naturopathic examiners** and defines naturopathy as meaning the use and practice of mechanical, medical and psychologic health sciences to aid in purifying, cleansing and normalizing human tissues for the preservation or restoration of health according to the fundamental principles of anatomy, physiology and applied psychology as may be required. Naturopathic practice employs among other agencies phytotherapy, dietetics, psychotherapy, hydrotherapy, zone-therapy, biochemistry, external applications, electrotherapy, mechanotherapy, mechanical and electrical appliances, hygiene, *first aid, sanitation and heliotherapy; provided, however,* that nothing in this act shall apply to or affect the practice of surgery, chiropractic or osteopathy or other healing art licensed in the state. S. 79 proposes that **applicants for a marriage license** must present a certificate signed by a qualified physician licensed to practice medicine and surgery in any state or United States territory indicating that the applicant has been given an examination and that in the opinion of the examining physician the applicant is not infected with syphilis in a *communicable stage. S. 84 proposes the creation of a state board of* **examiners for physical therapy technicians** and defines physical therapy as the therapeutic use of physical agents and comprises the use of physical, chemical and other properties of heat, light, water, electricity, massage and exercise. The proposal further requires that a physical therapy technician is one trained to apply the measures of physical therapy treatment which have been prescribed by a licensed member of the healing arts.

### Idaho

**Bills Introduced.**—H. 34 proposes the repeal of and the reenactment of the medical practice act of the state with extensive amendments. Among other changes, are the creation of an **independent state board of medical examiners**, provisions for the granting of temporary licenses and authorization to make use of the injunctive process in enforcing violations of the act. S. 51 proposes that the members of the board of any public hospital shall not be **liable** either individually or as board members **for the negligence of any employee**, servant or agent of the hospital which may result in injury or damage to any person, unless said board member shall have actively participated in his individual capacity in said act or acts of negligence upon which the action is based.

### Illinois

**Bill Introduced.**—H. 51 proposes the enactment of a comprehensive **hospital licensing law.**

### Iowa

**Bills Introduced.**—H. 240 and S. 220 propose that a trial court may direct a complainant, her child and the defendant, in **paternity actions,** to submit to one or more blood tests to determine whether or not the defendant can be *excluded as being the father of the child. The result* of the test shall be receivable in evidence but only in cases in which definite exclusion is established. H. 274, to amend the prenatal examination law, proposes to further require the physician to make a standard **test for the Rh factor.**

### Massachusetts

**Bill Introduced.**—H. 1901 proposes that **every examining board** for a profession, trade or business in the state shall have at least one public member who shall not be engaged in or qualified to engage in that particular profession. It would be the duty of such public member to represent the interests of the public and particularly to take cognizance of all attempts to adopt restrictive practices affecting the general welfare including all practices tending to prevent properly qualified persons from engaging in the profession, calling, trade or business and other restrictions and practices tending toward control thereof by small groups or discouraging individual initiative and free enterprise in the carrying on thereof and of all practices tending toward undue enhancement of prices for services to the public by persons engaged in such professions, callings, trades and businesses.

### Minnesota

**Bill Introduced.**—S. 197 proposes certain amendments to the law relating **to osteopathy** among which is the statement that osteopathy is a complete school of medicine and surgery based upon the fundamental principles of the osteopathic concept which are different from those principles recognized by other complete schools of medicine and surgery. Osteopathic schools are to be approved in accordance with standards and procedures filed with and approved by the State Board of Osteopathic Examiners. Standards and procedures for approval may be filed with the board of the national association of osteopathic physicians and surgeons to which belong the majority of the osteopathic physicians and *surgeons maintaining membership in a professional organization* and osteopathic hospitals or colleges shall be inspected and approved in accordance with these standards and procedures by that national association.

### New Mexico

**Bill Introduced.**—H. 46 proposes the creation of a state board of **naturopathic examiners** and defines naturopathy as including the diagnosis and practice of physiologic, psychologic, mechanical and material sciences of healing the human body; hygienic and sanitary measures incident to the care of the body and prevention of disease; corrective body manipulation and gymnastics; psychotherapy; use of heat, cold, air, water, light, earth, color, vibration, electricity or other forces and elements of nature; dietetics, which include the prescribing or administering of whole, raw, cooked, treated, concentrated or manufactured foods of such biochemical tissue building or normalizing products and cell salts as are found in a normal human body or necessary to maintain a body in a normal state of nutrition and health and the use of vegetal oils, fruits, seeds, barks, herbs, roots and vegetables, and such other elements and measures as may be developed by naturopathic science.

### North Dakota

**Bills Introduced.**—S. 226 proposes to prohibit the delivery of **barbiturates** to any person except by a pharmacist upon an original prescription from a person licensed by law to prescribe and administer barbiturates. The delivery by a practitioner in the course of his practice is exempted from the provisions of the proposal. S. 227 proposes that any graduate of any trade or professional school under the jurisdiction of the **state board of higher education** of North Dakota shall be licensed and entitled to practice that trade or profession in the state.

### Oklahoma

**Bill Introduced.**—H. 162 proposes to prohibit the delivery of **barbiturates** except by a pharmacist upon an original prescription from a person *licensed by law to prescribe and administer barbiturates.* The delivery of barbiturates by a physician in the course of his practice is exempted from the provisions of this proposal.

### Wyoming

**Bills Introduced.**—H. 39 proposes the creation of a **Board of Naturopathic Examiners** and defines naturopathy as "the science of natural methods of healing by the use of any and all the mechanical, chemical or material forces of Nature, including diagnosis and treatment by the physical, mechanical or chemical methods and further includes the use of herbs, minerals, diet, manipulation and physical therapy which is the use of air, water, light, electricity; but does not include the use of major surgery. S. 20 proposes to repeal the hospital licensing law enacted by the 1948 legislature. S. 71 proposes **the creation of an interim committee** to consider minimum standards for the licensing and operation of hospitals in the state.

# Coming Medical Meetings

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Academy of General Practice, Cincinnati, Netherlands Plaza Hotel, March 7-9. Mr. Mac F. Cahal, 231 W. 47th St., Kansas City, Mo., Ex[illegible]

American [illegible] gery, New Orleans, March 29-31. Dr. Bria [illegible] University Hospital, Washington, D. C., Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4, Secretary General.

[illegible] c Association, Chicago, Stevens Hotel, April [illegible] h.D., 1790 Broadway, New York 19, Secretary.

[illegible] Society for the Advancement of Plastic and [illegible] New York, Hotel Waldorf-Astoria, March 4. [illegible], 291 Whitney Ave., New Haven 11, Conn., Secretary.

Arkansas Medical Society, Little Rock, April 14-16. Dr. William R. [illegible] n Ave., Fort Smith, Secretary.

[illegible] Annual Clinical Conference, Chicago, Palmer [illegible] r. H. Kenneth Scatliff, 30 N. Michigan Ave.,

[illegible] Society, Dallas, Texas, March 14-17. Miss [illegible] edical Arts Bldg., Dallas, Executive Secretary.

Michigan Postgraduate Clinical Institute, Detroit, Book-Cadillac Hotel, March 23-25. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Mich., Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

Postgradute Assembly in Endocrinology, Association for the Study of Internal Secretions, Oklahoma City, Feb. 21-26. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary

Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.

Tennessee State Medical Association, Chattanooga, April 12-14. Dr. W. M. Hardy, 706 Church Street, Nashville 3, Secretary.

# GOVERNMENT SERVICES

## ARMY

### SHIPS DOCTORS WANTED

The Transportation Corps of the Department of the Army is accepting applications for civilian positions of ships doctors aboard Army transports. These vessels are operated by the Army for the International Refugee Organization in connection with the resettlement of displaced persons from Europe to various countries throughout the world. Doctors who are accepted for such employment join their ships at New York and sail for Europe and thence to South American ports or other ports throughout the world. Voyages generally are of 60 to 90 day duration with vessels returning to New York. The salary is $450 per month plus maintenance. Applicants may apply for one or more voyages and are not bound to serve beyond one voyage. They must be licensed physicians, U. S. citizens and available to leave on short notice. Information may be obtained by writing to: Crewing Section, New York Port of Embarkation, 1st Avenue and 58th Street, Brooklyn, N. Y.

### ARMY INSTITUTE OF PATHOLOGY

Dr. Jesse Edwards, of the Mayo Clinic, Rochester, Minn., lectured to the staff of the Army Institute of Pathology January 27 on "Pathology of Coarctation of the Aorta."

Dr. Henry A. Pinkerton, Kirkwood, Mo., who is at present studying malnutrition and erythroblastosis fetalis at the Institute of Pathology, presented a special lecture to the staff January 26 on "Inclusion Disease (Salivary Gland Virus Infection) as a Cause of Death in Infants."

Major Alexander R. T. Lundie of the British Royal Army Medical Corps reported to the Army Institute of Pathology for a six month study of the effects of atomic radiation.

Colonel Harvey A. Liversay, of Manila, Philippine Islands, reported to the institute January 24 for a two month study of general pathology.

Dr. Raymond A. Boyce, University of Minnesota, Minneapolis, reported to the institute January 15 for a six month study of urologic pathology.

## NAVY

### PSYCHOLOGY COMMITTEE MEETS AT SEA

The Secretary of the Navy invited the Committee on Aviation Psychology of the National Research Council to participate in a cruise on the aircraft carrier *Saipan* to Guantanamo Bay, Cuba, during which time the committee held its regular meeting. The Committee left Washington by air January 27 for Norfolk, Va., where they boarded the carrier for the cruise, returning February 5 by air. Among the subjects discussed were the Navy's current research program in aviation psychology and the progress made on investigations conducted by the Bureau of Medicine and Surgery of the Navy. The Committee also inspected the aviation facilities in the Guantanamo Bay area. The following members of the committee, together with a group of Navy officers, made the cruise: George Bennett, president, Psychological Corporation, New York; Dean R. Brimhall, head, Department of Research, Civil Aeronautics Administration; Glenn Finch, head, Department of Psychology, Office of the Air Surgeon, U. S. Air Force; Paul Fitts, head, Department of Psychology, Aero Medical Laboratory, Wright Field, Ohio; Eric Gardner, head, Department of Psychology, Syracuse University, Syracuse, N. Y.; Frank Geldard, head, Department of Psychology, University of Virginia; Morris S. Viteles, head, Department of Psychology, University of Pennsylvania, and chairman of Committee on Aviation Psychology; E. S. Ewart, secretary, Committee on Aviation Psychology; J. C. Flanagan, head, Department of Psychology, University of Pittsburgh, president, American Institute for Research; P. J. Rulon, dean, Harvard Graduate School, Cambridge, Mass., president, Educational Research Corporation; David Bakan, department of psychology, Ohio State University; A. C. Williams, head, department of psychology, University of Illinois; Capt. W. E. Kellum, M.C., U.S.N., School of Aviation Medicine and Reesarch, Pensacola, Fla.; Committee on Aviation Psychology; Lieut. Comdr. W. J. Robinson, U.S.N.R., Special Activities Branch, Aviation Medicine Division, Bureau of Medicine; Lieut. H. J. Older, U.S.N., Aviation Psychology Branch, Aviation Medicine Division, Bureau of Medicine; Lieut. W. F. Madden, M.S.C., U.S.N., Committee on Aviation Psychology; J. W. MacMillan, Medical Science Division, Office of Naval Research; Comdr. N. L. Barr, M.C., U.S.N., Special Activities Branch, Aviation Medicine Division, Bureau of Medicine.

## MISCELLANEOUS

### THE GOVERNMENT NEEDS NURSES

The U. S. Civil Service Commission announces an examination for staff nurse and head nurse, paying $2,974 and $3,727 a year respectively. Applicants must pass a written test and have had appropriate nursing education or a combination of such education and experience. Before being appointed, competitors must be registered as graduated professional nurses; however, applications will be accepted from nonregistered graduate nurses who are otherwise qualified. These positions are open in Washington, D. C., throughout the United States, in Alaska and in the Panama Canal Zone. For the Canal Zone, the maximum age limit is 35 years, and for staff nurse positions in the Indian Service, 40 years. These age limits are waived for persons entitled to veteran preference. Those interested may obtain application forms from Civil Service offices, first and second class post offices or from the United States Civil Service Commission, Washington 25, D. C. Applications must be received in the Commission's Washington office not later than March 29, 1949.

### PHARMACOLOGISTS WANTED

The U. S. Civil Service Examiners, Army Chemical Center, Md., announce that applications will be accepted by the Board at the above address for the positions of physiologists and pharmacologists, paying from $3,727 to $6,235 and $3,727 to $8,509 per annum respectively. Among the duties of the physiologists will be to conduct experimental programs designed to evaluate the physiologic effects of chemical agents on human subjects and to investigate the problems of shock and burns and to coordinate the research activities in physiology in one or more groups of scientists. Among the duties of the pharmacologists will be to delineate the effects and action of drugs and chemical agents and to conduct research programs designed to determine the toxicities of chemical agents by inhalation by the use of gas chambers, precision gassing experiments and analysis of concentration of chemical agents. The qualifications for these positions may be learned by writing to the Board of U. S. Civil Service Examiners, Army Chemical Center, Md. Application forms may be obtained at first or second class postoffices.

# Medical News

**(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)**

## ARKANSAS

**Meeting on Neuropsychiatry.**—The Veterans Administration Hospital, North Little Rock, will sponsor a neuropsychiatric meeting comprising lectures, seminars and demonstrations at the hospital February 28-March 1. Among the speakers will be:

Franz G. Alexander, Chicago, Psychosomatic Point of View in Modern Medicine.
Henry C. Chenault, Little Rock, Place of Psychiatry in Medical Education.
Jacob L. Moreno, New York, Value of Psychodrama and Group Psychotherapy.
Henry N. Peters, Ph.D., Little Rock, Abstract and Concrete Thinking in Personal Maladjustment.

Other speakers will be Drs. Edwin F. Gildea, St. Louis; Daniel Blain and Walter S. Freeman, Washington, D. C.; Harold W. Sterling, North Little Rock; Henry G. Schwartz, St. Louis; George S. Stevenson, New York, and Miss Inez Wilson, R.N.

## CALIFORNIA

**Tenth Anniversary of California Physicians' Service.**—On February 2 the California Physicians' Service observed the tenth anniversary of its founding. More than 710,000 Californians are beneficiary members, and the plan is served by 9,500 participating physicians. Each month the service pays an average of 23,000 claims on behalf of its members totaling more than $1,000,000. The California Physicians' Service, founded and sponsored by the California Medical Association, is a voluntary free enterprise which has proved capable of meeting the health needs of the people. Its administration is directed by a fourteen man board of trustees, eleven of them members of the medical profession.

## ILLINOIS

**Lectures for Laymen.**—The Illinois State Medical Society has arranged a series of public lectures on adult health problems in Oak Park. All of the lecturers are Chicagoans.

Feb. 15, W. W. Bauer, Fair Fat and Past Forty.
Feb. 22, David Slight, Nervousness and Its Causes.
March 1, Maurice H. Cottle, Seeing, Breathing and Hearing.
March 15, Howard A. Lindberg, Take Care of Your Ulcer.
March 29, Gilbert H. Marquardt, Growing Old Gracefully.
April 5, John T. Reynolds, What About Cancer?
April 12, James H. Hutton, How's Your Blood Pressure?

### Chicago

**Gifts to Surgical Department.**—Two gifts totaling $65,000 have been received by the Northwestern University Medical School from the Lois Grunow Memorial Clinic, Phoenix, Ariz. The sum of $50,000, to be known as the Lois Grunow Surgical Fund, has been allocated in support of the department of surgery and $15,000 has been designated as the Lois Grunow Professorship Fund to finance a professorship in the surgical department.

**Personals.**—Dr. Meyer A. Perlstein held a clinic in Hammond, Ind., February 16 for the Indiana Society for Crippled Children and Adults.——At the eighth Pan-American Congress on Tuberculosis in México, D. F., January 23-29, Dr. Edwin R. Levine spoke on the "Relation of Chronic Bronchial Infection to the Impairment of Pulmonary Function" and Dr. Henry C. Sweany on "A Pathologic Investigation of Tuberculosis Pleuritis."——Dr. Paul H. Hollinger, assistant professor of otolaryngology, University of Illinois College of Medicine, on January 18 gave an illustrated lecture at the Naval School of Aviation Medicine, Pensacola, Fla., on the treatment of throat diseases.

## KENTUCKY

**Rural Scholarship Fund.**—Up to January 1 thirty-two loans had been granted to twenty-one worthy medical students who on completion of training will practice in the rural districts of Kentucky. At a recent meeting of the Board of Trustees of the Scholarship Fund, which is sponsored by the Kentucky State Medical Association, applications of four additional students were approved.

**Citizens Health Committees.**—Under the direction of Dr. Bruce Underwood, state health commissioner, plans are under way to organize citizens health committees in every county of the state to represent the people in public health problems related to the work of the county health departments. These committees will assist the county health officers in developing and maintaining public health programs.

**Dr. Moore to Retire.**—Dr. John W. Moore, dean of the University of Louisville School of Medicine, has requested retirement to become effective in June. He was appointed dean in 1929. In 1936 he was the recipient of the faculty award of merit. Dr. Moore received his bachelor of science degree from Davidson College in 1906 and in 1912 was graduated from the University of Pennsylvania School of Medicine, Philadelphia.

## MICHIGAN

**New Heart Association.**—The Michigan Heart Association was established January 26 as an affiliate of the American Heart Association to develop and encourage research, education and community programs. Dr. Warren B. Cooksey, Detroit, was elected president and Dr. L. Fernald Foster, Bay City, secretary-treasurer. Initial plans were laid for Michigan two years ago, when the state medical society appointed a committee of fifteen physicians to study problems of organizing a Michigan chapter. The committee has had the assistance of prominent civic and lay persons.

**Appoint Rheumatic Fever Coordinator.**—Dr. Leon DeVel, Grand Rapids, became medical coordinator of Michigan's Rheumatic Fever Control Program January 1. He will integrate and standardize thirty rheumatic fever control centers throughout the state and aid in organizing additional centers. All the centers are maintained through a grant to the Michigan State Medical Society by the Michigan Society for Crippled Children and Adults. Dr. DeVel, a graduate of the State University of Liége, Belgium, located in Grand Rapids in 1928 and has practiced there continuously except for three years served in the Medical Corps of the Army of the United States.

## MINNESOTA

**Lectures on Conservation of Human Resources.**—The Minneapolis public schools are sponsoring an inservice course on "Conservation of Human Resources with Emphasis on the Handicapped Youth." Remaining lectures will be held in the auditorium of the Bryant Junior High School from 4 to 5:30 p. m. as follows:

March 1, Abe B. Baker, Epilepsy, Causes and Treatment.
March 8, John H. Gammell, Diseases and Defects of the Eye.
March 15, Conrad I. Karleen, New Methods Used in Plastic and Reconstructive Surgery.

## NEW MEXICO

**Clinical Society Lectures.**—The New Mexico Clinical Society has arranged the following lectures. At the February 25 meeting at the Veterans Administration Facility, Albuquerque, Dr. Hans Selye, Montreal, Canada, will lecture on "Hypertension as a Disease of Adaptation"; Dr. Maxwell M. Wintrobe, Salt Lake City, will present the March lecture; in May, Dr. Armand J. Quick, Milwaukee, will lecture on "The Hemorrhagic Diseases."

## NEW YORK

**Heart Disease Day.**—The local representative of the American Heart Association, the Rheumatic Fever and Heart Committee of the Tuberculosis and Health Association of Rochester and Monroe County, in cooperation with the Monroe County Medical Society, is planning teaching day for physicians on heart disease March 23 at the Rochester Academy of Medicine. All doctors and medical students are invited to attend free of charge. The program will close at 5 p. m. so that out-of-town doctors will be able to return home that night if they choose.

**Annual Clinical Day at Niagara Falls.**—The Third Annual Clinical Day of the Academy of Medicine of Niagara Falls will be held March 5 at the Hotel Niagara beginning at 9:30 a. m. The program is as follows:

Harry Gold, New York, Management of the Failing Heart.
J. Ernest Ayre, Montreal, Canada, Role of the Cervical Smear in General Medical Practice.
Louis J. Bailey, Detroit, Use and Abuse of Sex Steroids.
Lewis M. Hurxthal, Boston, Diagnosis of Angina Pectoris.
Edward L. Compere, Chicago, Low Back Pain.

**Postgraduate Lectures.**—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged postgraduate instruction for the Tompkins County Medical Society February 21 at 8:30 p. m. in Moore Hall, Cornell University Veterinary College, Ithaca. Dr. George P. Heckel, Rochester, will speak on "The Practical Applications of Endocrines in Gynecology." For the Queens County Medical Society a lecture has been arranged at the Society Building in Forest Hills March 11 at 4 p. m. when Dr. Charles L. Fox Jr., New York, will speak on "Plasma Therapy." The Oswego County Medical Society will hear Dr. Walter F. Rogers Jr., Syracuse, speak on "Thyroid Physiology and the Treatment of Thyrotoxicosis" February 22, 8:30 p. m. at the Fortnightly Club, Oswego.

## New York City

**Special Meeting at the Academy.**—The New York Institute of Clinical Oral Pathology will hear Dr. Charles F. Geschickter, Washington, D. C., speak on "Dental and Osseous Tumors of the Jaws" at the monthly conference February 28 at the New York Academy of Medicine at 9 p. m.

**Ward Teaching Program.**—City Hospital, Welfare Island, announces a practical ward teaching program under the direction of Dr. Carl Reich, attending physician, to be given February 1-May 1. Twenty-four staff members will take part in the teaching. The program is free to members of the medical profession. Inquiries may be made in the board room at the hospital.

**Cornell Alumni Day.**—Cornell University Medical College will have a scientific program on Alumni Day, March 24, as follows:

S. Bernard Wortis, New York, Medical Mission to Poland—1948.
Irvine H. Page, Cleveland, The Nature of Arterial Hypertension.
Thomas H. Ham, Boston, Diagnosis and Mechanism of Hemolytic Anemias.
William S. McCann, Rochester, N. Y., Some Neglected Aspects of Cardiology.

**Appoint Professor of Obstetrics and Gynecology.**—Dr. Robert G. Douglas has been appointed professor of obstetrics and gynecology at Cornell University Medical College and obstetrician and gynecologist in chief to New York Hospital, effective July 1, succeeding the late Dr. Henricus J. Stander. Dr. Douglas received his medical degree from McGill University, Montreal, 1924. After study at the University of Rochester School of Medicine and in several European clinics he has held various positions at the New York Hospital-Cornell Medical Center.

**Tuberculosis Society Election.**—Dr. Donald B. Armstrong, New York, was elected president of the New York Tuberculosis and Health Association, Inc., at the annual meeting January 25, succeeding Dr. Kendall Emerson. Dr. Armstrong, who is in charge of the Metropolitan Life Insurance Company's nursing, health educational and welfare program, has been active in tuberculosis control since 1916, when he began the "Framingham Tuberculosis and Health Experiment." He has been a member of the board of directors of the New York Tuberculosis and Health Association for sixteen years and prior to election as president was chairman of the executive committee. Other officers elected were Myron I. Borg Jr., secretary, and Harry P. Davison, treasurer.

## NORTH CAROLINA

**Fellowships in Medicine.**—On July 1 Duke University School of Medicine will have available several two year fellowships with stipends of $2,400 the first year and $3,000 the second year. Only those who have completed three years training in internal medicine, or a satisfactory equivalent, will be eligible for these positions, which are designed to prepare the candidate for the practice of internal medicine. The following places will be available: hematology and allergy, pulmonary diseases, gastroenterology, hypertensive cardiovascular and renal diseases, metabolic diseases, cardiology, general internal medicine and therapeutics. For information address Dr. Eugene A. Stead Jr., Duke University School of Medicine, Durham.

## OKLAHOMA

**Society News.**—Dr. Warren O. Nelson, professor of anatomy at the State University of Iowa College of Medicine, Iowa City, will speak at the regular meeting of the Tulsa County Medical Society February 21 at 8 p. m. on "Testicular Disfunction."

**Blood Center at Tulsa.**—The Tulsa County Blood Center opened in the community welfare building January 11 under the sponsorship of the local chapter of the American Red Cross and the Tulsa County Medical Society. It will serve patients in all of Tulsa's seven hospitals. Under a contract entered into between the center and the participating hospitals the patient pays only a single charge of $10 per pint of blood, which covers hospital laboratory service. The Red Cross has organized a recruitment program. Dr. Mabel M. Hart, former city schools physician, will be director of the center.

## OREGON

**Special Society Meeting.**—The Oregon State Society of Anesthesiologists will hold its regular monthly meeting in the University of Oregon Medical School Library March 9 at 8 p. m. A paper on "Use of a Disposable Polyethylene Tubing for Continuous Spinal Analgesia" will be read by Dr. David C. Boals of the Veterans Administration Facility in Portland. All interested physicians are invited to attend.

## SOUTH DAKOTA

**Dr. Hohf Awarded First Fifty-Year Pin.**—Dr. Silas M. Hohf, Yankton, has been awarded the South Dakota State Medical Association's first fifty-year practitioner pin, thus making him the only member of the Fifty-Year Club at the present time. In the state are other eligible physicians who will receive awards during 1949. Dr. Hohf received his M.D. degree in 1897 at the Illinois Medical College. He began practice in Yankton in 1897 and has been serving there for fifty-one years with interruptions for service in World War I and postgraduate training. For fourteen years he was in the surgery department of the University of South Dakota School of Medical Sciences, Vermillion, terminating that affiliation in 1929.

## VIRGINIA

**Seminar on Immunity and Allergy.**—In connection with the Stuart McGuire Lectures a Seminar on Immunity and Allergy will be given at the Medical College of Virginia, Richmond, March 17-18. Among the speakers will be:

William C. Spain, New York, Hay Fever.
Horace S. Baldwin, New York, Treatment with Special Reference to Intractable Asthma.
Wingate M. Johnson, Winston-Salem, N. C., Allergy in Relation to Medicine as a Whole.
Harry L. Alexander, St. Louis, The Stuart McGuire Lecture I, The Changing Concept of Allergy, Underlying Mechanisms.
Robert Chobot, New York, Management of the Asthmatic Child.
Walter L. Winkenwerder, Baltimore, Urticaria and Angioneurotic Edema.
Oscar Swineford Jr., Charlottesville, Va., Role of Infection in Allergy.

In the second Stuart McGuire Lecture Dr. Alexander will consider "Changing Concept of Allergy, Clinical Examples."

## WASHINGTON

**Society Aims to Modernize Commitment Law.**—The Washington Society for Mental Hygiene is introducing a bill in the state legislature to bring the legal provisions of the state law into line with the progressive thinking of modern psychiatry. Washington's commitment law relating to psychiatric care in state institutions allows only for taking care of those determined as "insane" and "feeble-minded" by court order. The law would make possible voluntary and preventive commitments for diagnosis and study as well. Among other things, the bill provides for psychiatric help rather than punishment for drug and alcoholic addicts, sexual psychopaths and psychopathic delinquents.

## WEST VIRGINIA

**State Association Acts to Promote Voluntary Sickness Insurance.**—The public relations committee of the West Virginia State Medical Association has inaugurated a program to carry to the people of this state a direct campaign designed to prove that voluntary sickness insurance is preferable to any form of compulsory health insurance. The program for a statewide public relations campaign, which got under way forty-eight hours after the council approved the project, will be broadened in scope when committees have been set up by the various component societies. In a letter mailed the middle of January to the secretary of each component society, the new committee asks for the appointment of a public relations committee composed of one tenth of the members. Each will be asked to get in touch with ten other members, so that practically all doctors in organized medicine may participate in the program. The doctors will then be asked to explain the campaign to at least twenty of their friends, lay and professional groups, that an educational campaign is being sponsored by the state medical association to fight socialized medicine. Each society is asked to set up a speakers' bureau and to provide speakers for professional and lay groups. The expenses for the educational and public relations program will be financed from voluntary contributions of $25 per member, which the council has asked all members of the state medical association to pay in addition to the American Medical Association assessment of $25.

## WISCONSIN

**Dr. Haessler Appointed Professor of Ophthalmology.**—Through an anonymous benefactor, Marquette University, Milwaukee, has established the first full time clinical professorship in its School of Medicine, the chair of ophthalmology. Dr. F. Herbert Haessler, Milwaukee, has retired from private practice to accept the professorship. He will manage the eye clinic and dispensary, which have been a part of the medical school for twenty-five years, teach medical students and eventually develop a training program for young men who are interested in becoming eye specialists. It was specified by the benefactor that the chair be established as a memorial to the late Dr. John L. Yates, Milwaukee surgeon and Marquette faculty member, and his sister, the late Mrs. Carol M. Allis.

## GENERAL

**Multiple Sclerosis Society Changes Address.**—The National Multiple Sclerosis Society has announced the removal of its offices to 270 Park Avenue, Suite 7G, New York 17.

**Southern Surgeons Club.**—The annual meeting of the Southern Surgeons Club will be held at the Duke University School of Medicine and Duke Hospital, Durham, N. C., March 14-15. Included in the program is an address by Dr. Michael E. DeBakey, Houston, Texas. Members of the university staff will present papers Monday afternoon and Tuesday morning.

**Meeting of Otorhinologic Society.**—The American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery will hold a stated meeting February 24 at the Hotel Waldorf-Astoria, New York. Speakers at the scientific session at 8 p. m. will be:

Max L. Som, New York, Plastic Closure of Pharyngostomy Following Laryngectomy.

George A. Friedman, New York, The Traumatic Face.

William A. McNichols, Dixon, Ill., Complicated Fractures of the Maxilla.

**Influenza and Measles.**—According to the U. S. Public Health Service, the total number of influenza cases reported in the first four weeks of this year was 63 per cent below the corresponding total for 1948 (which was also the median for the five years 1944-1948). The total number of reported cases of measles in the first four weeks of the year is about 15,041, the largest number reported for the corresponding period since 1938.

**Meeting to Honor Professor Forbes.**—The Eastern Association of Electroencephalographers will hold a testimonial meeting in honor of Dr. Alexander Forbes, professor of physiology, Harvard University, February 19-20 in the Building C Amphitheater, Harvard Medical School, Boston. The address opening the scientific session will be given by Dr. Hallowell Davis, St. Louis. A dinner will be given in honor of Dr. Forbes at 7 p. m. Saturday at the Hotel Continental, Cambridge. He has served on the staff of Harvard University since 1912.

**Heart Association Drive for Five Million Dollars.**—The American Heart Association opened its nationwide drive for $5,000,000 to combat heart disease February 7 and will continue the campaign to February 28. The organization includes thirty-eight affiliated local heart associations and campaign committees in 505 communities throughout the country. The major portion of the funds collected this year will be used for research and for the development of local heart associations to provide community cardiac services. Founded by leading heart specialists as a scientific society in 1922, the American Heart Association was reorganized in 1947 to admit lay members to its governing bodies. It is today the only national voluntary health agency devoted exclusively to combating diseases of the heart and circulation.

**Accident Toll for 1948.**—The National Safety Council, Chicago, reports that 98,000 persons were killed in accidents during 1948 and 10,300,000 were injured at an economic loss of $7,200,000,000. Home accidents again led the list as the nation's number 1 accident killer. The 1948 toll was 2 per cent below 1947; while all accident classifications except home showed decreases, the over-all decrease was due principally to the sharp drop in public accidents other than motor vehicle, notably drowning and disaster tolls. This decline in public deaths plus the reduction in motor fatalities, which was numerically modest but large in relation to soaring travel miles, were the brightest spots in the accident picture. Deaths from accidents in 1948 as compared to 1947 were as follows:

| | 1948 | 1947 | Change, Percentage |
|---|---|---|---|
| All accidents | 98,000 | 99,579 | —2 |
| Motor vehicle | 32,000 | 32,697 | —2 |
| Home (civilian) | 34,500 | 34,000 | +1 |
| Occupational (civilian) | 16,500 | 17,000 | —3 |
| Public (civilian, not motor vehicle) | 16,500 | 17,500 | —6 |
| Military personnel | 1,200 | 1,300 | —8 |

In 1948 the all-accident death rate was 67.1 per hundred thousand population, the lowest rate since the previous low of 68.4 in 1921.

Falls caused the death of 27,000 persons, a 3 per cent increase over 1947; deaths from burns 8,400, a 1 per cent increase; drownings 6,900, 7 per cent under 1947; firearms 2,300, representing an 8 per cent drop. Catastrophes in which the toll was at least 5 lives totaled 1,100, according to the Metropolitan Life Insurance Company, as compared with 2,100 in 1947. One catastrophe in 1940 caused as many as 50 deaths, the Oregon-Washington flood. Five others that caused between 25 and 50 deaths were three airplane crashes, the Illinois tornado and a swamped launch.

Vehicle milage in 1948 is estimated at 7 per cent above 1947. The death rate per 100,000,000 vehicle-miles was estimated on the basis of preliminary data at 8.1—the lowest rate on record. Among the forty-five states which have reported complete motor vehicle death tolls for the year, Rhode Island led the twenty-two states reporting decreases over 1947, with a decrease of 41 per cent. Among the cities with 200,000 population, Syracuse, N. Y., had the largest reduction in fatalities, 46 per cent below 1947. Richmond, Va., was second and Los Angeles was third.

Disabling injuries from home accidents numbered 5,200,000, and the resulting wage loss, medical expense and overhead costs of insurance totaled $700,000,000. Nearly all increase occurred among persons 65 years and older. Occupational accidents totaling 16,500 caused 3 per cent fewer deaths than in 1947, although the total all-industry employment increased about 2.5 per cent. Disabling injuries from work accidents numbered about 1,950,000. The economic loss from occupational accidents was about $2,600,000,000. Coal mine deaths in the first eleven months of the year dropped to 916, 12 per cent below last year's figure. Railroad employee fatalities were 425 in the first nine months, a decrease of 21 per cent, and likewise injuries in the nine months dropped 13 per cent to a total of 23,486. Deaths to workers from all accident causes totaled 48,000—16,500 on the job and 31,500 off the job, a decrease of 2 per cent from 1947. Injuries numbered about 4,550,000, representing a total time loss of 410,000,000 man-days. Five fatal accidents occurred in the domestic passenger-carrying operations of scheduled air transportation during the year, with a death toll of 98, including 83 passengers and 15 crew members. Passenger death rate per 100,000,000 passenger-miles based on preliminary information was 1.4 compared with 3.2 for 1947. Railroad accidents during the first nine months showed a death toll of 2,762, a 12 per cent decrease from 1947, with passenger deaths showing a 40 per cent drop to 35. Trespasser deaths numbered 1,209, a decrease of 16 per cent from 1947. The estimated accident death toll for military personnel for 1948 was 1,200, an 8 per cent drop from 1947.

## CORRECTIONS

**Personal.**—In The Journal, January 29, page 317, the name of Dr. Frank L. Rector of Evanston should be changed to Lieutenant Edgar M. Rector of Portland, Ore., who was a recipient of the Navy Cross Medal for his service as medical officer with the infantry battalion in the Saipan and Tinian engagements in the recent war.

**Society Election.**—The American Academy of Dermatology and Syphilology meeting in Chicago in December retained Dr. Earl D. Osborne, Buffalo, N. Y., as secretary-treasurer and did not elect Dr. Louis A. Brunsting to the office as was stated in The Journal, January 29, page 320. Dr. Brunsting is secretary of the American Dermatological Association.

**Bladder Stone.**—In the Query and Minor Note with this title in The Journal, January 29, page 346, the second sentence in the answer reads: The female urethra is capable of wide dilation but normally can only be stretched to 35 F, which would be 105 mm. in diameter. The 105 mm. should have been 11.6 mm.

## Marriages

Lewis William Wannamaker, St. Matthews, S. C., to Miss Hallie Walker Etheridge of Whitakers, N. C., September 11.

Keith Millner Oliver to Dr. Priscilla Lowell Foote, both of Purcellville, Va., at Durham, N. C., September 4.

James Arthur Williams, Indianola, Miss., to Dr. Rowena Jean Romer of San Francisco, in December.

William Clayton Barr, Virginia Beach, Va., to Miss Ivee Elizabeth White of Richmond, September 11.

William Rhea Bond, Beckley, W. Va., to Miss Veronica Valerie Scearce of Richmond, November 13.

John Hays Sharp, Columbus, Ohio, to Miss Beverly Jane Brock in Alliance, recently.

James F. Houghton, Jersey City, N. J., to Miss Jeanne Bull at Westfield, January 29.

Albert Sternbach to Miss Jacqueline Oppenheim, both of New York, December 5.

Alvin Sherwood Medoff, Brooklyn, to Miss Rita Katz of New York, December 9.

# Deaths

**Oliver Wendell Holmes Mitchell** ⊕ Syracuse, N. Y.; born in Lancaster, Mo., Aug. 17, 1886; University of Missouri School of Medicine, Columbia, 1908; associate professor of bacteriology and pathology at his alma mater prior to 1914, when he joined Syracuse University College of Medicine as associate professor of bacteriology and public health, subsequently becoming professor of bacteriology, hygiene and sanitation, and later professor of bacteriology and public health; member of the House of Delegates of the American Medical Association from 1943 to 1948; past president of the Syracuse Academy of Medicine and of the Onondaga County Medical Society; served for a long period on the New York State Medical Society Council Committee on Public Health and Education and in 1938 became chairman of the committee and director of the society's postgraduate medical education program; in this capacity he worked closely with the New York State Health Department; served on advisory committees to the state health department and at the time of his death was on the department's advisory committee on rheumatic fever; from 1914 to 1918 served as city bacteriologist and in 1922, commissioner of health; member of the American Association of Pathologists and Bacteriologists and the Society of American Bacteriologists; affiliated with the Hospital of the Good Shepherd, Syracuse Memorial and St. Joseph's hospitals; died December 20, aged 62, of coronary thrombosis.

**Clinton Kitto Smith** ⊕ Kansas City, Mo.; born in Dunlap, Iowa, April 17, 1883; University of Colorado School of Medicine, Denver, 1907; an Associate Fellow of the American Medical Association; member of the American Urological Association; past president of the Southwestern Branch of the American Urological Association; specialist certified by the American Board of Urology; served on the faculty of the University of Kansas School of Medicine, Kansas City, Kan.; an officer during World War I; affiliated with Children's Mercy and Kansas City General hospitals; consulting surgeon at the Ellis Fischel State Cancer Hospital in Columbia; formerly editor of the *Jackson County Medical Society Weekly Bulletin;* died in Johnson County, Kan., November 21, aged 65, of carcinoma of the prostate.

**Ernest Milton Watson** ⊕ Buffalo; born in Warwick, R. I., in 1884; Johns Hopkins University School of Medicine, Baltimore, 1913; professor of urology at the University of Buffalo School of Medicine; specialist certified by the American Board of Urology, Inc.; formerly associated with the U. S. Public Health Service; member of the American Urological Association; past president of the Central Section of the American Urological Association; fellow of the American College of Surgeons; affiliated with Children's Hospital, Edward J. Meyer Memorial Hospital, U. S. Marine Hospital, State Institute for Malignant Diseases and Buffalo General Hospital, where he died December 5, aged 63, of massive cerebral hemorrhage due to cerebral arteriosclerosis.

**Herman William Hundling** ⊕ Little Rock, Ark.; State University of Iowa College of Medicine, Iowa City, 1915; at one time a fellow in surgery at the Mayo Foundation in Rochester, Minn.; a captain in the American Expeditionary Forces in France during World War I; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; associate professor of surgery at the University of Arkansas School of Medicine; affiliated with Missouri Pacific Hospital, St. Vincent Infirmary, Arkansas Children's Home and Hospital and Baptist State Hospital; died January 8, aged 57.

**George Jacob Kastlin** ⊕ Pittsburgh; University of Pennsylvania School of Medicine, Philadelphia, 1924; assistant professor of medicine at the University of Pittsburgh School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists; served during World War II; medical director of the Skin and Cancer Foundation; affiliated with Montefiore and St. John's General hospitals; died in Presbyterian Hospital December 31, aged 48.

**Nathaniel Emmons Paine,** Newton, Mass.; born in New Hartford, N. Y., in 1853; Albany (N. Y.) Medical College, 1875; professor emeritus of psychiatry at the Boston University School of Medicine; fellow of the American College of Physicians; member of the American Psychiatric Association and the American Medical Association; served as trustee and chairman of the board, Westboro (Mass.) State Hospital; affiliated with Massachusetts Memorial Hospital in Boston and Newton Hospital; formerly vice president of the West Newton Savings Bank; died in Walpole, November 30, aged 95, of duodenal ulcer and cervical and lumbar spinal arthritis.

**Harry Sherwood Allen** ⊕ Ironton, Ohio; Miami Medical College, Cincinnati, 1895; past president and secretary of the Lawrence County Medical Society; for many years city health commissioner; died in the Lawrence County General Hospital recently, aged 75, of heart disease.

**Alice Gates Bugbee,** Milford, Conn.; Cornell University Medical College, New York, 1903; member of the American Medical Association and of the Medical Society of the State of New York; died December 5, aged 78, of coronary heart disease.

**Frederick Joseph Cicotte,** Chicago; Loyola University School of Medicine, Chicago, 1916; member of the American Medical Association; died Feb. 19, 1948, aged 67, of coronary thrombosis.

**Eugene Edward Lamoureux,** Wethersfield, Conn.; Tufts College Medical School, Boston, 1935; member of the American Medical Association; director of the bureau of preventable diseases and formerly epidemiologist of the Connecticut State Department of Health; died November 22, aged 41, of coronary thrombosis.

**James Percy McAnulty,** San Angelo, Texas; University of Texas School of Medicine, Galveston, 1911; fellow of the American College of Surgeons; served during World War I; during World War II served as examining physician of Tom Green County Selective Service Board No. 1; one of the founders of the San Angelo Medical and Surgical Clinic; served on the medical board and as chief of obstetrics and pediatrics at the Shannon West Texas Memorial Hospital, where he died November 12, aged 61, of coronary heart disease.

**Angus Dugald Macintyre,** Spokane, Wash.; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1901; F.R.C.S., Edinburgh, Scotland, 1909; member of the American Medical Association; served as a captain in the Canadian Army during World War I; died in Sacred Heart Hospital October 11, aged 71, of pulmonary embolism and cerebral embolism.

**Ransom Andrew Nockton Jr.,** Crowley, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1938; served overseas in the medical corps of the U. S. Naval Reserve during World War II; died November 30, aged 34, of burns received in a fire of undetermined origin.

**Glen DeWitt Sheets,** Williamsport, Ohio; Ohio State University College of Medicine, Columbus, 1920; past president and vice president of the Pickaway County Medical Society; served during World War I; died in Circleville October 17, aged 55, of coronary thrombosis.

**Joseph L. Soldinger,** Chicago; Loyola University School of Medicine, Chicago, 1916; member of the American Medical Association; died in the Norwegian American Hospital December 19, aged 53.

**Adelbert Elmer Torrens,** West View, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1902; member of the American Medical Association; served during World War I; affiliated with Allegheny General Hospital in Pittsburgh; died November 13, aged 74, of cardiovascular renal disease.

**Thomas Turnbull Jr.** ⊕ Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1887; an Associate Fellow of the American Medical Association; died in Emergency Hospital, Washington, D. C., December 23, aged 83, of cardiorespiratory failure.

**Harry Ellsworth Wilson,** Centralia, Ill.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1901; member of the American Medical Association; died in St. Mary's Hospital November 13, aged 76, of coronary occlusion, cholelithiasis and prostatic hypertrophy.

**John Mayer Wilson** ⊕ Mobile, Ala.; University of Alabama School of Medicine, University, 1907; member of the International College of Surgeons; fellow of the American College of Surgeons; affiliated with Providence Hospital; died in New Orleans November 12, aged 64, of coronary occlusion.

**Ernest George Wollenweber,** Los Angeles; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1904; formerly on the staffs of St. Joseph's and Graham hospitals in Keokuk; died October 17, aged 70, of cerebral hemorrhage.

**James R. Womack,** Houston, Mo.; Northwestern Medical College, St. Joseph, 1893, member of the American Medical Association; served in the state legislature and as county coroner; died in the Barnes Hospital, St. Louis, November 8, aged 80.

### Gastroscopy

At the Medical Society of London an important discussion took place on gastroscopy. Dr. Avery Jones said that modern gastroscopy dated from the development of the Wolf-Schindler instrument in Germany, which was introduced to this country in 1934. It had been remarkably improved by Mr. Hermon Taylor. Examination was done mostly with patient under local anesthesia, though it could be done with him under general. With morphine or hyoscine premedication discomfort was minimal. The Hermon Taylor instrument gave much better definition with untoward reaction in only 1 in 700 cases. The advantage of gastroscopy was increased accuracy of diagnosis. It was a valuable supplement to roentgen rays. It might more frequently demonstrate a gastric ulcer. Sometimes it would show a healed ulcer, or it might reveal a diverticulum. It gave a more accurate prognosis of healed ulcer than the roentgenogram.

Mr. Hermon Taylor said that in 1939 he demonstrated an adaptation of the Wolf-Schindler instrument which allowed it to be bent forward at will and enabled a near or distant view of the mucosa to be obtained. It could be flexed round so as to afford a view of a pyloric tumor. The gastroscope had brought a new accuracy to the study of gastric conditions. Previously the diagnosis in roentgenologically negative cases was largely a matter of opinion based on the test meal, the examination of the stools for blood and the clinical history, with the result that all the cases came to be lumped together as "gastritis." The gastroscope exploded this conception of universal gastritis to explain otherwise undiagnosed dyspepsias. Gastritis should be redefined; it is an inflammation of the mucous membrane recognizable by edema, loss of translucency, petechiae, excessive mucus or mucopus and perhaps erosion. An unusual pattern or irregularity at the pylorus might simulate carcinoma, and the gastroscope would help to elucidate this problem. Some authorities maintain that all gastric ulcers should be excised because 10 per cent became malignant. But if the gastroscope is used and the healing of the ulcer is watched there is no question of missing any malignant change. But examination with the gastroscope is not to be lightly undertaken. Mistakes and accidents do occur. The commonest mistake, which Mr. Taylor said he had made many times himself, is diagnosing malignant changes in an ulcer on one gastroscopic examination.

### The Pulheems System of Medical Classification

In 1943 the Canadian Army adopted a new system of medical classification, for which the chief credit is due to Major General Brock-Chisholm. It provided for the first time a concise method of expressing the physical and mental capacities of a person and was so successful that it has been adopted by the British fighting services and the Ministry of Labor. The examination is carried out in seven subdivisions, called qualities, and from the initial letters of these the name Pulheems is derived. They are P, physical capacity; U, upper limbs; L, locomotion; H, hearing; EE, eyesight; M, mental capacity, and S, stability (emotional). The duplication of E is due to noting separately visual standard of each eye. The letter R is inserted after the other letters to show that the condition noted is remediable. There are 8 degrees under each quality.

The medical assessment of any man under the system is based on functional efficiency at the conclusion of training. The code number provides a complete indication of the fitness, physical and mental, of the man for employment under varying conditions. The code number can be reduced to a simple two letter code for administrative application, as has already been done in the Army. Thus we have the following: FE, employable on full combatant duties in any part of the world (FE, forward everywhere); FT, employable on full combatant duties in any area in temperate climates (FT, forward temperate); LE, normally employable in the lines of communication or base area, but may be employed in the forward area in any role which is not primarily a fighting one; LT, normally employable in lines of communication in temperate climates only; BE, employable only in the base area in any part of the world (BE, base everywhere); BT, employable only in the base area in temperate climates; HO, employable in the protected area in the United Kingdom only (HO, home only).

### Stricter Control of Dangerous Drugs

The problem of the control of dangerous drugs has recently received attention, in consequence of anxieties expressed by the international authority which administers the narcotic control conventions, the Permanent Central Opium Board. Two new British requirements are that persons authorized to be in possession of dangerous drugs must take proper care of them, and authorized sellers of poisons must keep stocks under lock and key. Pharmacists have the responsibility imposed on them of satisfying themselves of the genuineness of all prescriptions for a dangerous drug.

Drug addiction is not a serious problem in Britain. The latest figures show that addicts number about 383, all of whom obtain their supplies by prescription. The principal drugs of addiction are morphine and heroin. Few take cocaine, and their number is decreasing. The manufacture of dangerous drugs is controlled by a system of licensing and supervision. According to the government report the addict or would-be trafficker has little chance of obtaining dangerous drugs and the possibility of organized traffic with Indian help is discounted.

### The Achievements of BCG Vaccination

The tuberculosis department of the Oslo Public Health Service has for many years carried out BCG vaccination on carefully planned lines in order that, by strict roentgenologic and tuberculin control, its merits may be gaged by scientific standards. Dr. Gerhard Hertzberg, who is on the staff of the tuberculosis department, has just published an exhaustive study of BCG vaccination carried out in the period 1932-1946. His 224 page book, published in English with the above title by Johan Grundt-Tanum (price 15 kroner) deals with the more than 18,000 persons vaccinated with BCG in the period under review. Conscious of the many statistical pitfalls awaiting him, he has secured the assistance of Miss Julie Backer, Ph.D., who is the departmental chief of the Central Statistical Bureau.

The most original and perhaps the most interesting feature of this study concerns the tuberculin reactions (Pirquet and Mantoux) following BCG vaccination. Dr. Hertzberg has learned to distinguish between the comparatively mild tuberculin reaction to BCG vaccination and the more violent tuberculin reaction to a superimposed accidental infection with virulent tubercle bacilli of the human type. These two reactions differ in several respects which are familiar to the staff of the tuberculosis department. But Dr. Hertzberg has concentrated attention on the measurement in millimeters of the reactions as being the most objective criterion, and he emphasizes the practical importance of distinguishing between the two. His final conclusion that BCG vaccination is harmless and also affords considerable protection against tuberculosis should do much to promote the more extensive employment of this measure.

### Red Blood Cell Diameters in Liver Diseases

Dr. Gerhard Larsen's M.D. thesis, published with the foregoing title at the end of 1948, is the outcome of an investigation lasting from the beginning of 1943 to October 1946. As he points out, several observers have already remarked on an increase in the mean diameter of the erythocytes in diseases of the liver. But there is no agreement over the frequency and causes of this phenomenon. Dr. Larsen has evolved a certain technic in the measurement of the erythrocytes, and he has followed the changes in their diameters in a number of patients throughout the course of their hepatic diseases. The diseases studied were acute hepatitis (26 cases), chronic hepatitis (32 cases) and cholecystitis or cholelithiasis (14 cases). In all the cases of damage to the cells of the liver, the diameter of the erythrocytes was found to be increased while the mean corpuscular volume remained the same. A comparison of these cases with cases of pernicious anemia suggested that there is a fundamental difference in the blood cell population in the two groups. But when patients with pernicious anemia were treated with liver extract, the blood cell population was indistinguishable from that of hepatitis. Dr. Larsen argues that the disturbances in the blood observed in hepatitis as well as in pernicious anemia are due to a disordered maturation of the precursors of the erythrocytes in the bone marrow. Some tentative experiments suggest that nicotinic acid plays a part in this process.

This study is also an instructive sign of the times, and it is indicative of a shift of emphasis in medicine for which the mathematician-statistician is responsible. The biologist of yesterday, happy in his ignorance of all but the elements of statistics, must read with mixed emotions this study which is so freely seasoned with mathematical formulas. His choice lies between exercising blind faith in what these formulas are supposed to show and going to school once more to learn this new science. Only a generation ago he would have made his choice (neither of the two!) with a contemptuous reference to statistics as the last word in mendacity. Today he has an uneasy feeling that men of the Dr. Larsen school are better equipped than himself for getting to the heart of scientific problems. "The old order changeth. . . ."

### Professor Olav Hanssen Retires

Having reached the age limit, Professor Olav Hanssen retired at the end of 1948 from his post as professor of medicine at the University of Oslo and as head of Department A of the Rikshospital. His valedictory address, delivered on December 11 in the packed lecture hall of the hospital, was a summary of, and commentary on, his philosophy of life. For twenty-five years he has taught this philosophy in the lecture hall and practiced it in his wards. As a lecturer, he has held his audience spell bound by his well disciplined histrionic gifts, with the aid of which he has driven home much practical wisdom. As a clinician in the wards he has taught his students to listen, silently and patiently, to what the patient himself has to say. Alert and quizzical, he has been a potent antidote to bumptiousness in his juniors. These are but a few of the reasons why this great little man, with quick, peremptory movements, has endeared himself to his patients and commanded the affection and respect of his students and nurses. At the end of his valedictory address he was given an enthusiastic ovation by his colleagues, and on the same day his recently painted portrait was unveiled in the Rikshospital. His successor is Professor Paul A. Owren, whose work on a new clotting factor in the coagulation of the blood has already given him an international reputation. The post of second in command in Department A of the Rikshospital has been awarded to Dr. Gerhard Larsen, whose recent M.D. thesis on the distribution of red blood cell diameters in hepatic diseases deserves special notice.

### Eradication of Malaria in Holland

Formerly Holland stood on record as an unhealthy country. Maybe records exaggerated; nevertheless, things happened there which would not have been out of place in tropical countries but were very much so in Northwestern Europe. The Salsburg settlers, driven from their Austrian home to perish in the Zealand swamps, offer one example. The well known fate of the British Army in the isle of Walcheren is another. One may argue that the country was not so much to blame as faulty organization in settling immigrants and billeting troops in little known surroundings, but the country was blamed for it all the same. It was pronounced as unhealthy as Italy, and for the same reason: intermittent fevers. From 1845 onward they were called malarial fevers, and so the notion arose that Holland was highly malarious. Half a century later this was apparently confirmed by Schoo's diagnosing vivax malaria in hundreds of his patients. However, malarial fevers of former days were highly fatal; modern ones are not. For that reason doubt has arisen whether the old intermittent fevers were malaria in the modern sense of the word.

This doubt, however, does not detract from the fact that there is much malaria in this country, limited to the provinces with predominantly brackish water; in one of them only, the province of North Holland, it constitutes a health problem of some magnitude. Even there malaria is not a constant feature of the countryside; bad years are separated by long intervals of almost complete exemption from the disease. Korteweg and his successors, in the village of Wormerveer, recorded epidemic exacerbations round about 1880, 1901, 1922 and 1946. Similar ups and downs occur in other parts of the province.

Aquatic conditions being distinctly unfavorable to antilarval measures, sanitary authorities, since 1935, have concentrated on killing adult mosquitoes by spraying human habitations. They were justified in doing so by the excellent research work done by Professor Swellengrebel (Indian Institute, Amsterdam) and his co-workers on the habits of the main vector, Anopheles maculipennis atroparvus. Especially interesting was the finding of Swellengrebel and de Buck. They found these mosquitoes infected inside human habitations only (not in animal habitations), from the middle of August till the end of December; they acquire their infection no later than the end of October. As a rule, their bite causes no illness till after an incubation of six to nine months; i. e., from April till August, the usual term of the Dutch malarial season.

Accordingly, malaria control in Holland consists in killing infected Anopheles; i. e., in spraying the houses where they are likely to occur. These are the houses inhabited by parasite carriers, persons who had malaria in the current year or in one of the two preceding years.

From 1935 until 1946 pyrethrum was sprayed. This had to be repeated every fortnight from August till October, as in mosquitoes sporozoites mature in about fifteen days during the season of infection. With this method good results were obtained in villages but not in towns, because the method depends on an adequate selection of the houses to be sprayed; that is, on an accurate knowledge of malaria incidence, which is more difficult to obtain in towns than in villages.

With the support of the International Health Division of the Rockefeller Foundation DDT has replaced pyrethrum. Wolff and Kraan found its residual effect in Holland lasting for five months at the lowest estimate. Consequently, one spraying is carried out in July, well in advance of the transmission season; it easily covers that whole season. This simplification obviates the need of selecting the houses to be sprayed. Henceforward all human habitations are to be treated, and animal habitations as well.

The first year, 1947, showed satisfactory results: In the treated villages and towns malaria was practically stopped in 1948. It continued in untreated villages, although at a lower level than in 1947, the epidemic being on the wane.

DDT residual house spraying is to be extended over the whole of the province. It is confidently expected that it will eventually lead to the complete eradication of this nonfatal but nevertheless troublesome disease.

## Correspondence

### DESTRUCTIVE LESIONS OF THE NOSE

*To the Editor:*—In the Jan. 1, 1949 issue of The Journal, page 49, the Paris Letter deals with the treatment of leprosy. In the second paragraph, the writer mentions "erythematous lupus of the face, with a large excavation of the nose" and "an ulcerative erythematous lupus; the soft parts of the nose were destroyed."

These statements are misleading to those who are not versed in dermatology. The name erythematous lupus, or lupus erythematodes, as used here, should be "lupus vulgaris" or "tuberculosis lupoides." Destructive lesions of the tissues, especially of the nose, do not occur (except in extremely rare instances), in patients with lupus erythematosus. Destructive lesions of the nose, however, are common manifestations of lupus vulgaris, a tuberculosis of the tissues.

While it is to be assumed that the patients mentioned were suffering from destructive lesions caused by the tubercle bacillus, it should be borne in mind that destructive lesions of the nose may also be caused by numerous other diseases, such as syphilis, gangosa, rhinopharyngitis mutilans, blastomycosis, yaws and cancer.

Fred Wise, M.D., New York.

### CONTRACEPTIVE AGENTS

*To the Editor:*—I have been reading with great interest the excellent paper on contraceptive agents by Eastman and Seibels in The Journal, January 1.

In my former practice in Baden-Baden, Southern Germany, now in the French Zone (practice limited to obstetrics and gynecology), I recommended a simple contraceptive for indigent families, especially when the health of the mother was weak, when the number of living children was more than 4 or 5, and when the earning power of the husband was weakened also by sickness or by economic insecurity. I advised the patient to buy packages (dozen) of tampons of lamb's wool, suspended on a thread; I prescribed an ointment of 10 per cent boric acid and 1 per cent lactic acid and advised the patient to put a small portion of this ointment on the surface of the tampon, which was introduced before intercourse. This has the advantage that there is not great diminution of friction, which diminishes the sexual feelings for man and woman, and it is also less expensive. People with little education spill much jelly, when used in the form advised by Eastman and Seibel, and the expense is considerable. Also the occlusion of the cervix by the tampon of lamb's wool is more perfect than the occlusion by a pessary which often is dislocated. The introduction of a tampon is far easier than the introduction of a diaphragm. The tampon is removed with the thread after intercourse. The expense of the wool tampon is about 10 cents. The wool tampon is of course preferable to a tampon made of cotton, as it is elastic and does not collapse when moist.

Robert Kuhn, M.D., Friendsville, Tenn.

### HYPERHEPARINEMIA, WHITE EMBOLI AND LEUKERGY

*To the Editor:*—With reference to Alfred L. Copley's article, "Hemorrhagic Diathesis in Hiroshima," The Journal (137:145 [May 8] 1948), I should like to make the following suggestions:

1. In a number of experiments conducted in our laboratories at the beginning of 1948 I had definite evidence which convinced me that heparin in vitro and in vivo (even in doses smaller than needed for the prevention of blood coagulation) causes agglutination of thrombocytes—thus contradicting the opinion hold by most writers (Jorpes, Solandt and Best, Boyd, Whitby and Britton and others). I am glad that the findings of Copley and his co-workers are the same. Independently of the agglutination of thrombocytes, however, heparin causes also a clumping of the white blood cells, mainly granulocytes. It can be proved that this agglutination of leukocytes is independent of the presence of platelets, because it takes place also in the blood of an animal deprived of platelets by the use of antithrombocytic serum after Ledingham. The conglomerations disintegrate at the temperature 46 to 48 C; an excessive quantity of salt—e. g., 2 to 4 per cent sodium chloride—also breaks them up.

2. The same agglutination of thrombocytes and leukocytes takes place in peptone and anaphylactic shocks. This phenomenon could be explained by hyperheparinemia, which appears, according to Quick, Jaques and Waters, in such states.

3. The phenomenon, however, takes place also in pregnancy (in women from the fourth month of pregnancy to the third month post partum), after an injection of histamine, in febrile diseases, after an intravenous injection of killed bacteria, after foreign protein injections and after an intrapleural injection of turpentine in animals.

4. The white emboli described by Copley can be seen not only after heparin, but also, for example, after an injection of killed bacteria or peptone. I have made such observations on an auricle of the ear of a young mouse, a very proper object to this purpose. It may be that some observations described by M. H. Knisely, E. H. Bloch and his co-workers (Sludged Blood, *Science* 106:431, 1947) concern the same phenomenon.

5. To the described phenomenon of the agglomeration of leukocytes I have given (1942) the term "leukergy" (Current Comment, J. A. M. A. 135:578 [Nov. 1] 1947; *Lancet* 2:765 [Nov. 22] 1947), and I have described the test for detecting it in blood samples from veins or skin capillaries. An interesting feature of this phenomenon is the fact that the conglomerations reveal a tendency to cytologic homogeneity; i. e., some groups consist of granulocytes, other groups of lymphocytes, and so on. It seems reasonable to suppose that in the mechanism of leukergy specific serologic factors play some part (autoagglutinins or perhaps autoglutinins?), and also an unspecific increase in the leukocytes' and thrombocytes' stickiness, caused, perhaps, in all cases by heparin. Leukergy probably plays a part in the migration of leukocytes, has also an indirect role in phagocytosis and belongs, therefore, to the phenomena of inflammation and immunity. On the basis of our studies (*Polski Tygodnik lek.* 2:1329, 1947; *Texas Rep. Biol. & Med.* 5:156, 1947; *Ann. Univ. Curie-Sklodowska* (Section D) 1:335-349, 1946; ibid. 3:181-197, 1948) on this phenomenon the conclusion can be drawn that tests of leukergy and observations of its degree and also of the kind of conglomerated cells will be of clinical value.

Ludwik Fleck, M.D.,
Professor of Microbiology, Lublin, Poland.

# Medical Motion Pictures

## FILM REVIEWS

**The Institute of Rehabilitation and Physical Medicine.** 16 mm., color, sound, 800 feet (1 reel), showing time twenty minutes. Prepared in 1948 by Howard A. Rusk, M.D., Director of Institute; Donald A. Covalt, M.D., Clinical Director, and George G. Deaver, M.D., Professor of Clinical Rehabilitation, New York University, N. Y. Produced by Jacob Sarnoff, M.D., Brooklyn. Procurable on loan (service charge) from the New York University Film Library, 26 Washington Place, New York, or on purchase from the Institute of Rehabilitation and Physical Medicine, 325 East Thirty-Eighth Street, New York 16.

This film describes the work of the institute and illustrates the many types of seriously disabled persons undergoing rehabilitation. Training in ambulation is stressed, and 2 young women with complete paralysis of the lower extremities are shown. The views of the prosthetic appliances center, the experimental kitchen for the disabled housewife and the department of physical medicine are of interest. A message of hope is conveyed to the rehabilitation of paraplegics, hemiplegics, quadriplegics and also patients with advanced poliomyelitis, cerebral palsy, arthritis and injuries of the peripheral nerves.

The picture does bring to the attention of the medical profession the development of this new and important institute, which attempts to achieve the maximal function and adjustment of the individual by preparing him physically, mentally, socially and vocationally for the fullest possible life compatible with his abilities and disabilities. This film is worthy of consideration and should be seen by all persons interested in the rehabilitation of disabled persons.

Unfortunately the photography is amateurish. In many of the scenes the camera has been "hand held," there is much "panning" (swinging of the camera from side to side) and poor lighting, considerable shaking of the picture and much swinging to unimportant detail are apparent. Despite the unfortunate inferiority of parts of the photography, the script is good and the narration is excellent.

**Anesthesia.** 16 mm., color, silent, 400 feet, showing time fifteen minutes. Prepared and produced in 1947 by Wallace M. Shaw, M.D., with the cooperation of E. A. Rovenstine, M.D., and E. M. Papper, M.D., Corona, N. Y. Procurable on loan or purchase from: The American Society of Anesthesiologists, 745 Fifth Avenue, New York.

This motion picture depicts the present day scope of anesthesia, and its basic aim is building up the specialty of anesthesiology. It has a sense of drama without being maudlin, and the story of the duties of the anesthesiologist unfolds with smoothness and drama.

The film is excellent and is suitable for administrative groups in hospitals, premedical students and beginning medical students, staff and student nurses and some lay groups. If it could be lengthened to include more data it could be used for teaching senior medical students and anesthetists. The photography is fairly good, though the picture is obviously a home-made production.

## NEW MOTION PICTURE ADDED TO A. M. A. MOTION PICTURE LIBRARY

**Examination of the Breast for Early Cancer.** 16 mm., color, sound, 590 feet (1 reel), showing time twenty minutes. Prepared in 1948 by The State of California, Department of Public Health, and the California Medical Association Cancer Commission. Produced by Billy Burke Production, Hollywood, Calif. Procurable on loan (Service Charge $3.00) from Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

This film illustrates a method of examination of the female breast for early cancer. The author stresses the essentials of a proper examination, namely, gaining the patient's confidence, good lighting, careful inspection, palpation and transillumination. The author rightfully emphasizes the fact that one should never cause unnecessary manipulation of a breast which is the seat of cancer. He also points out that only by microscopic examination can the exact nature of a lesion of the breast be accurately diagnosed. Also, transillumination can only be properly performed in an absolutely darkened room. This film would be of particular value as an educational aid and is recommended to state and county medical societies, residents, interns and medical students. The color photography is excellent.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc.: *Written.* July 15. Various locations. Final date for filing application is April 15. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Avenue, New York 27.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part I.* Various Centers, April and May. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: New York, May 11-14, Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City

American Board of Pathology: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Surgery: *Written.* Various Centers, March 1949. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska: * Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas: * Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination,* Los Angeles, Feb. 28-March 3. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

Connecticut: * Hartford, March 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

District of Columbia:* *Reciprocity,* Washington, March 14. Sec., Dr. George C. Ruhland, 4130 Municipal Building, Washington.

Florida: * *Examination,* Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

Indiana: *Examination.* Indianapolis, June. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Iowa: *Examination.* Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kentucky: *Examination.* Louisville, June 15-17. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

Maine: Portland, March 8-9. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination,* Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Massachusetts: *Examination.* Boston, March 8-11. Sec., Dr. George L. Schadt, 413 E. State House, Boston.

Mississippi: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Montana: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

Nebraska: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

Nevada: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

New Hampshire: Concord, March 10. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

New Mexico: Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

North Carolina: *Endorsement.* Pinehurst, May 9. *Examination.* June 23-25. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

Ohio: *Endorsement.* Columbus, April 5. *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

PUERTO RICO: *Examination.* Santurce, March 1. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

SOUTH CAROLINA: Columbia, June 27-29. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

TEXAS: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

UTAH: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B Loomis, 324 State Capitol Bldg., Salt Lake City.

VIRGINIA: *Examination.* Richmond, June 17-18. *Reciprocity.* Richmond, June 16. Dr. K. D. Graves, 631 First St., S.W., Roanoke.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Feb. 21-26. Sec.-Treas., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: *Examination.* Tucson, March 15. Sec., Dr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

COLORADO: *Examination.* Denver, Mar. 2-3. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

DISTRICT OF COLUMBIA: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

FLORIDA: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

MINNESOTA: *Examination.* April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

OKLAHOMA: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Portland, March 5 and June 18. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

SOUTH DAKOTA: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, March 21-22. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

WISCONSIN: Madison, April 2., Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

## MEDICOLEGAL ABSTRACTS

**Paternity: Blood Grouping Tests Inadmissible to Prove Paternity.**—In a suit by the plaintiff mother to have the defendant husband declared to be the father of a child born to her, the trial court, over the defendant's objection, granted the plaintiff's request that the defendant be required to submit to a blood test. From such action of the trial court, the defendant appealed to the Supreme Court of South Dakota.

It was the defendant's contention on appeal that the action of the trial court compels him to give evidence which may tend to incriminate him. The motion of the plaintiff on which the trial court entered the order under review, said the Supreme Court, simply moves the court for an order requiring defendant "to submit to a blood test to determine whether or not the defendant, James Brigham, is the father. . . ." The affidavit in support of said motion states in substance the issue of paternity as presented by the pleadings and the willingness of the plaintiff and her child to submit to blood tests and demands that the defendant submit to a test "to determine the paternity of said child." The affidavit then nominates a physician to conduct the tests. It is readily observed, said the Supreme Court, that the plaintiff's application was predicated on the erroneous assumption that paternity may be established by blood tests.

In a prior case (*State v. Damm,* 64 S. D. 309, 266 N. W. 667) the Supreme Court recognized blood tests as admissible in proceedings in which paternity is at issue and held that the trial court has inherent power and authority, in the exercise of its reviewable discretion, to order the taking of blood for purposes of making tests if the results, in the court's opinion, are likely to be helpful in ascertaining the truth. The paternity of a child, the court continued, cannot be determined by testing and classifying blood from the defendant and comparing the same with like tests of blood of the plaintiff and the child. Such tests may in some instances prove nonpaternity. They never establish paternity. In another former case decided by this court (*Smith v. Smith,* 24 N. W. (2d) 8) it was held that the results of blood tests not tending to exclude either the husband or another man under suspicion were not helpful. No possible benefit could result to the plaintiff, concluded the Supreme Court, should blood grouping tests be made such as were sought by her. We believe, therefore, that the showing in support of the order appealed from was insufficient to establish good cause under the South Dakota statutes. Accordingly, the action of the trial court was reversed and the trial court's order requiring the submission of the defendant to a blood test was set aside.—*State ex rel. Wollock v. Brigham, 33 N. W. (2d) 285 (S. D., 1948).*

**Prenatal Injuries: Liability for Negligent Injuries to Unborn Child.**—Can a child, after birth, recover for prenatal injuries suffered by reason of the negligence of another?

In Mays v. Weingarten, the infant plaintiff was born prematurely because of the defendant's negligence in permitting his automobile to collide with a bus in which the plaintiff's mother was a passenger. The trial judge sustained the defendant's demurrer, so the plaintiff appealed to the court of appeals of Ohio, Mahoning County. The plaintiff contended that under the state constitution, providing that "all courts shall be open, and every person, for an injury done him in his . . . person, . . . shall have remedy by due course of law, and shall have justice administered without denial or delay," he was a person and, therefore, entitled to maintain his suit. A person, said the court of appeals, is defined in Black's Law Dictionary and Webster's New International Dictionary as "(1) A rational being; a being possessing or forming the subject of, personality; hence, an individual human being. (2) A human being; one as distinguished emphatically from things or animals. (3) The bodily form of a human being; body outward appearance." The difficulty with the plaintiff's argument, said the court of appeals, is that when injured "in (his) the mother's womb he had no separate existence of his own. When born he became a person . . . His full rights as a human being sprang into existence with his birth." In the absence of a statute, said the court of appeals, the general rule is that a child may not recover for prenatal injuries. Since there is no statute in Ohio relating to this matter, the court of appeals concluded, we must follow the general rule. The judgment of the trial court in favor of the defendant was accordingly affirmed.

In Williams v. Marion Rapid Transit, Inc., the infant plaintiff was born prematurely when her mother was injured by a fall from the steps of one of the defendant's buses. The trial court in this case, also, sustained the defendant's demurrer and an appeal was accordingly taken by the plaintiff to the court of appeals of Ohio, Marion County. Eminent and many decisions are adverse to a recovery, said the court of appeals. Many of the courts rule that precedents are binding and that there is no relief, while at the same time the courts indicate that natural justice points the other way. "It is a general rule of law that in the absence of a statutory provision requiring a different result, a prenatal injury affords no basis for an action in damages in favor of the child. The doctrine of the civil law and the ecclesiastical and admiralty courts that an unborn child may be regarded as in esse for some purposes, when for its benefit, has been characterized as a legal fiction not indulged in by the courts to the extent of allowing an action by an infant for injuries occasioned before its birth. A reason advanced for this rule is that there is no person in being at the time of the accident to whom the defendant owes a duty of care." Biologically speaking, said the court, the life of a human being begins at the moment of conception in the mother's womb. However, there is a medical distinction between the terms embryo and viable fetus. The embryo, the court continued, is a fetus in its earliest stage of development, especially before the end of the third month, but the term viable means that the fetus has reached such a stage of development that it can live outside the uterus. It is the opinion of this court, the court of appeals concluded, that an infant as a existing viable child in its mother's womb has a cause of action after birth for injuries caused by the negligence of another and that neither a statute nor a fiction of law is necessary to allow a recovery by such child. Accordingly the action of the trial court in overruling the defendant's demurrer was overruled and the case was remanded to the trial court for further proceedings.—*Mays v. Weingarten, 82 N. E. (2d) 421 (Ohio, 1948). Williams v. Marion Rapid Transit, Inc., 82 N. E. (2d) 423 (Ohio, 1948).*

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American J. Digestive Diseases, Fort Wayne, Ind.

**15**:321-358 (Oct.) 1948

Pruritus in Hepatic Disease. S. E. Schechter and H. Necheles.—p. 321.
*Problems in Diagnosis and Treatment of Non-Calculous Gall Bladder. H. L. Segal, H. A. Friedman and J. S. Watson Jr.—p. 325.

Clinical Evaluation of New Laxative. A. D. Blake Jr.—p. 336.
Nutrition in Geriatrics—Psychologic and Somatic Aspects. R. Ginzberg.—p. 339.

**The Noncalculous Gallbladder.**—Segal and his co-workers apply the term noncalculous gallbladder to one which is the cause of abdominal distress without the presence of calculi either in the gallbladder itself or in its afferent or efferent tributaries. Disease may or may not be present in such a gallbladder. The authors employ the classification of Russell and his associates as an aid in formulating diagnostic criteria. They have divided gallbladder disorders into (1) disorders resulting in disturbances in filling and emptying mechanism of gallbladder, (2) disorders resulting in disturbances in the concentrating function of the gallbladder and (3) disorders in blood and metabolism resulting in disturbances of the gallbladder. The history, roentgenogram, duodenal drainage and study of the bile pigments in the urine are evaluated as diagnostic factors. The history and the roentgenogram are the two most important means by which the diagnosis is made. Duodenal drainage is necessary in many cases to determine the presence of stasis and occasionally of the type of infection. The recent conception of regurgitation jaundice and the simplified technics to study bile pigments may be of aid in determining the presence of liver damage. The authors discuss the place of surgical and medical management in relationship to the type of disturbance. In the medical management the amount and kind of fat used will mainly depend on its effect on symptoms. The selection of bile salt therapy depends on the type of gallbladder derangement. Oxidized unconjugated bile salts are suggested for flushing. The unoxidized conjugated natural bile salts are recommended for a concentrated bile.

Insulin Mixtures and Conservation of Insulin. R. M. Wilder.—p. 532.
*Liberal Regimen of Treatment of Diabetes. H. J. John.—p. 537.
Fatal Anuria, Nephrotic Syndrome and Glomerular Nephritis as Sequels of Dermatitis of Poison Oak. D. A. Rytand.—p. 548.
Primary Carcinoma of Liver. H. L. Holley and G. Pierson.—p. 561.
Primary Carcinoma of Liver. S. D. Spatt and D. M. Grayzel.—p. 570.
So-Called Extrarenal Uremia: Study of 20 Cases. F. D. Murphy, B. J. Peters and R. C. Newman.—p. 574.

**Treatment of Diabetes.**—John advocates an almost free diet with adequate control as reflected in the blood sugar level throughout the day, not merely in the fasting blood sugar. If the fasting blood sugar is normal, the noon sugar elevated and the evening blood sugar normal, this is acceptable. If the fasting blood sugar is normal and the evening levels high, some insulin should be added to the protamine zinc insulin in the morning to take care of this postprandial rise. If all three blood sugars are elevated, the protamine zinc insulin should be increased and the subsequent checkup will show whether or not some insulin should be added to the protamine zinc insulin. Both insulins should be given in the same syringe, in one injection, so as to diminish the discomfort. It does not matter whether some of the insulin is changed over to protamine zinc insulin. The important thing is not "how much of the insulin is changed over" but "how it works." With such a regimen the patient loses no time from work and is not overburdened with impractical details which disturb his equanimity.

### American Journal of Psychiatry, New York

**105**:241-320 (Oct.) 1948. Partial Index

Genesis of Hostility in Children. Lauretta Bender.—p. 241.
Dynamic Mechanisms Underlying Some Forms of Cerebral Dysfunction. S. Brock.—p. 246.
Minnesota Multiphasic Personality Inventory Patterns Before and After Insulin Shock Therapy: Preliminary Report. W. M. Hales and W. Simon.—p. 254.
Clinical Significance of Minnesota Multiphasic F Scale Evaluated in Experimental Neurosis. J. Brozek and B. C. Schiele.—p. 259.
Psychodynamic Considerations in Gilles De La Tourette's Disease (Maladie Des Tics): With Report of 5 Cases and Discussion of Literature. E. Ascher.—p. 267.
Lymphocytes in Psychoneuroses: Preliminary Observations. H. C. Shands and J. E. Finesinger.—p. 277.
*Mental Attitude of Cancer Patient to His Disease. B. J. Ficarra.—p. 304.

**Mental Attitude of Patient with Cancer.**—According to Ficarra the reception by patients of the verdict of chronic heart disease or nephritis does not produce any unusual psychologic conflict. To suggest cancer stirs a tempest of mental agony. Whenever possible the relatives or friends are told of the presence of cancer. Though the patient is rarely informed, he may suspect the cause for his distress. When the patient with cancer is youthful, the reception of this knowledge usually causes more emotional upset in relatives and friends than in the patient himself. Young adults have a greater capacity for adapting themselves to their fate than their elders. In the geriatric age group, the sense of approaching death is ever present. Old patients fear it and are more nervous about it than youths. Rarely has a cancer patient acquired a true psychosis. In patients with gastrointestinal cancer azotemia usually develops with its associated mental retardation. Other types of cancer patients are overcome by toxemia, or are so completely morphinized that they are deprived of complex perceptions, ratiocination and intensive thought.

Toxemia of Pregnancy. R. D. Bryant.—p. 1018.
Infectious Mononucleosis—Review of Disease. W. W. Dalton.—p. 1021.

**Industrial Diseases of Chest.**—Hamlin points out that it is most difficult to overcome the effect on a worker when once he has been told by his family physician that shadows observed in the roentgenogram of his chest are the result of silicosis, when actually there has been no significant exposure. Such interpretations frequently result in unjustified claims for compensation as well as unnecessary apprehension on the part of the employee. The author discusses the chest conditions the roentgen patterns of which may simulate silicosis. He stresses that unless there has been definite exposure to hazardous dust, as demonstrated by actual counts of respirable particles of free silica in the breathing zone of the worker, one should be extremely cautious about making an interpretation of silicosis even though the roentgenogram strongly suggests it.

**Fungi in Presence of Radioactive Isotopes.**—Pearson and his co-workers found that certain shipments of radioactive isotopes ($P^{32}$ and $I^{131}$) were contaminated with fungus spores. These spores were observed under the microscope and cultures of them were identified. As a result of this observation, the authors decided to test the sensitivity of numerous stock cultures of fungi. They exposed cultures of forty-three different types of fungi to radioactive iodine, radioactive phosphorus and high voltage roentgen rays. The cultures were grown on Sabouraud's medium until there was a good growth and spores were visible microscopically. Enough sterile sodium chloride solution was added to each tube to bring the water level to the top of the agar slant. Twenty microcuries of radioactive phosphorus or iodine was added to each tube. They were left at room temperature for forty-eight hours; subcultures were then made and incubated at room temperature. Cultures of the same fungi were exposed to an equivalent amount of high voltage roentgen rays and then subcultured. Since $P^{32}$, $I^{131}$ and roentgen rays were not lethal and no gross morphologic changes in the fungi were noted, a pathogen and a nonpathogen, after exposure to the radioactive solutions, were inoculated intravenously into animals to check alteration in pathogenicity. Alternaria, the nonpathogen, could be followed with the Geiger counter after injection; when the animal was killed after fifteen days no lesions were found, and the organism could not be cultured from postmortem material. The animals receiving Blastomyces dermatitidis died in twenty-four days or less of generalized blastomycosis. Radioactive substances apparently do not alter the morphology or the pathogenicity of fungi, and solutions of radioactive iodine and phosphorus are not self sterilizing.

**Vagus Nerves in Treatment of Peptic Ulcer.**—Tests carried out by Winkelstein on ambulatory patients with uncomplicated duodenal ulcers and on normal controls demonstrated that both large (15 units) and small (5 units) doses of insulin given intravenously provoke a markedly higher acid response in patients with duodenal ulcers than in normal persons. This suggests that the central vagus nucleus is hyperirritable to drops in blood sugar in ulcer patients. Earlier experiments revealed that sham feeding which strongly stimulates the vagus reflexly gave a higher response in ulcer patients than in normal persons. In a third series of studies it was shown that the nocturnal secretion of ulcer patients is increased at least threefold in acidity and volume over that of normal persons. Physiologists agree that the chief stimuli for the night secretion are mediated through the vagus nerves. *Irrespective of the ultimate* course of ulcer, the vagus nucleus and nerves play a central part in the ulcer problem. Medically, intragastric drip therapy with milk-sodium bicarbonate solution or diluted alumina gels is of considerable value in controlling the night secretion, and surgically vagotomy seems important in the attack on the vagi. The author favors partial gastrectomy combined with vagotomy, since it gives the least motor disturbance and the highest percentage of postoperative nocturnal achlorhydrias. He regards gastroenterostomy plus vagotomy less favorably and more in the light of an experiment. He is opposed to simple bilateral vagotomy alone because of recurrences and untoward symptoms resulting from the vagotomy.

**Prognosis in Pulmonary Tuberculosis.**—The potentialities of a minimal lesion discovered by periodic roentgenographic examination of the chest are becoming, according to Allison, a vital question as larger numbers of such foci are being uncovered in mass surveys. A program for control of tuberculosis based solely on an initial history, medical examination and periodic roentgenograms of the chest has been in operation at the Eastman Kodak Company, Rochester, N. Y., for twenty-five years. In an earlier report the author recorded the results of the program for more than 25,000 war workers during a five year period. Now he presents observations made on the course of the disease in a group of employees with clinical and/or roentgenographic evidence of pulmonary tuberculosis who were followed for ten or more years. Eighty-five employees in a group of 93, the majority of whom worked more than twenty years, never had clinical evidence of active infection. The serial roentgenograms of the majority of this group showed changes in minimal lesions from relative "softness" to resolution, calcification or contraction over the years. Active pulmonary tuberculosis may develop after long periods (upward of ten years) of apparent inactivity. It may appear in persons with "negative" roentgenograms of the chest as late as the forty-fifth year of life. Relatively short periods of treatment for a minimal lesion are sufficient to return most persons to their usual work. The incidence of relapse is low.

*Association of High Blood Pressure, and Increased Pulse Rate As Manifestation of Hyperglycemia in Chronic Eye, Ear, Nose and Throat Conditions. E. H. Coachman.—p. 379.

**High Blood Pressure and Pulse Rate as Manifestation of Hyperglycemia.**—Coachman asserts that patients with hyperglycemia do not always show glycosuria because of a high renal threshold, which prevents the sugar from being passed from the blood into the urine. This repeated retention produces headaches, photophobia, lacrimation, dizziness, increased postnasal discharge, paresthesias, generalized fatigue, transient scotomas and diplopia, which may progress to nausea and vomiting. Erroneous diagnoses of Ménière's syndrome, "sinus trouble," "loss of equilibrium" and allergic manifestations are often made. Many of these patients have no sugar in the urine and have normal fasting blood sugars, and so the existence of hyperglycemia is often missed. The two hour dextrose tolerance test, however, will reveal hyperglycemia. Elevated blood pressure and fast pulse rate in the presence of a normal or subnormal temperature are frequently enough associated with hyperglycemia to warrant doing two hour dextrose tolerance tests routinely in these cases. Overweight, short neck, stout persons predominate in this group, and cataracts are so frequently seen that hyperglycemia is suspected of being a contributing cause. Latent vertical phoria is found in persons with elevated blood pressure and fast pulse, and on inclusion of the vertical correction in their lenses, the dizziness, photophobia, lacrimation and asthenopic symptoms are further relieved, even after control of the blood sugar. Latent vertical phoria should enter in the differential diagnosis in suspected cases of Ménière's syndrome and in "sinus" or "sick" headaches.

Unilateral Hydrosalpinx with Torsion without Involvement of Ovary: Case Report. R. H. Kazmierski.—p. 1416.

**Surgical Relief of Pain in Shoulder.**—Jonas points out that pain in the shoulder and upper extremity is frequently dismissed as "neuritis" or treated with heat and salicylates with indifferent or poor results. In a large proportion of cases the pain is caused by a lesion amenable to surgical or orthopedic correction. Understanding of the neurologic pathways mediating such pain is essential. Two of the author's patients with cervical ribs had undergone previous cholecystectomy without relief; another with cervical intervertebral disk had led the restricted life of an anginal cripple. The author discusses pains caused by lesions of the cervical intervertebral disks and by cervical ribs; also the scalenus anticus syndrome, lesions involving the peripheral nerves and those involving the autonomic nervous system, such as Raynaud's disease and Weir Mitchell's causalgia. Surgical procedures are available for relief of these conditions and deserve a wider appreciation.

*Painless Appendectomy. F. C. Guzman and O. J. Reyes.—p. 429.

**Painless Appendectomy.**—Guzman and Reyes say that a short-acting barbiturate and narcotic, in the form of seconal sodium® and morphine in combination with the usual local infiltration anesthesia, has been found to render painless such short-lasting operations as elective appendectomies. This anesthetic regimen was employed in 890 elective appendectomies, including 285 acute cases, and it was found successful except in 4 cases. Timing is important. Seconal sodium®, 3 grains (0.2 Gm.), should be given one hour before, and morphine sulfate, ¼ grain (15 mg.), thirty minutes prior to the operation. It has been observed that with this regimen the patients are brought to the operating room, operated on and taken back to ward either fast asleep or half asleep, but all of them have remarked that the operation was painless.

**Rabies Virus in Chick Embryo Blood.**—Koprowski and Cox point out that the question whether rabies virus is present in the blood of infected animals has been debated for several decades. The authors found in the course of studies on rabies infection in the developing chick embryo that rabies virus is distributed throughout the tissues of the embryo with no particular affinity for the central nervous system. These results suggested a hematologic spread of the virus and, therefore, presence of the virus in the blood of the embryo. The authors describe experiments dealing with the latter possibility. They inoculated the Flury strain of rabies virus by the yolk sac route into 7 day old chick embryos. By means of intracerebral injections into mice, the virus was recovered from the chick embryo blood secured from the third to the fifteenth postinoculation day. Similar results obtained in two series of experiments seem to exclude the possibility of a major experimental error. While these experiments do not prove or disprove the infectiousness of mammalian blood from rabies-infected animals, they do indicate a completely different mechanism of dissemination of the virus in embryonated eggs.

**Eastern Equine Virus from Arthropods.**—Howitt and his associates point out that within recent years several neurotropic viruses have been recovered from the chicken mite, Dermanyssus gallinae (De Geer), and it has been shown not only to harbor the viruses in nature but to maintain at least one of them by transovarian passage. During the summer of 1947 sporadic cases of encephalitis in children had been reported from several areas of central Tennessee. Many of the cases were in rural or semirural districts and were often associated with the presence of domestic fowl. On Aug. 23, 1947, approximately 300 chicken mites, Dermanyssus gallinae, were removed from the roosts of a chicken house near Shelbyville, Tenn. The authors have recovered the virus of Eastern equine encephalomyelitis from chicken mites and from a mixture of chicken lice. Neutralizing antibodies for this virus were present in the serums of a few chickens and one cow. Further confirmation is needed to prove the role of mites and especially of lice as true vectors of this virus.

**Celiac Disease.**—Sheldon emphasizes that celiac disease should be distinguished from other causes of steatorrhea in childhood, particularly from fibrocystic disease of the pancreas. The age of onset of these two conditions is different; children with celiac disease develop normally for several months up to a year or more after birth, while those with pancreatic fibrosis present symptoms from birth. The meconium may be of such stiff consistency as to give rise to symptoms of intestinal obstruction within a few days of birth, often with fatal results, and the name "meconium ileus" aptly describes this aspect of fibrocystic disease of the pancreas. Another point of contrast lies in the appetite. Children with celiac disease have a notoriously fickle appetite, but infants with pancreatic fibrosis have a good, even voracious appetite. The odor of the stools in pancreatic fibrosis is even more repellent than that of the celiac stool; besides the probable excess of fat and starch in both stools the pancreatic stool contains unabsorbed and decomposed dietary protein. Trypsin, lipase and amylase are produced in normal amounts by children with celiac disease, but are either absent or much reduced in children with pancreatic fibrosis. In the early months of life, before celiac disease develops, the infants thrive satisfactorily on a diet of either breast milk or cows' milk. The age of onset of celiac disease usually coincides with the stage when the diet is expanding from milk to mixed feeding. The greatest change at this age is the addition to the diet of starch in rapidly increasing amounts. While children with celiac disease pass an excessive amount of fat in their stools, the view that fat in their diet should be severely reduced is difficult to maintain; indeed, the evidence would suggest that attention ought to be directed primarily toward their difficulty with starches.

**Pteroylglutamic Acid (Folic Acid).**—Davidson reviews the physiologic, biologic and clinical effects of folic acid and related compounds and offers a new concept of the pathogenesis of megaloblastic blood formation in the different groups of megaloblastic anemia. He describes the therapeutic effects of folic acid in 85 patients with a variety of anemias with and without thrombopenia and leukopenia. It was found that a hemopoietic response occurred only in patients with megaloblastic anemia, although improvement in alimentary symptoms and general health might occur in certain cases of the sprue syndrome with a normoblastic anemia. Folic acid is not recommended for the treatment of addisonian pernicious anemia because of the dangers of development of neurologic complications. Folic acid is the agent of choice in the treatment of the pernicious (megaloblastic) anemia of pregnancy, the pernicious anemia of infants and nutritional (tropical) megaloblastic anemia, and in those cases of the sprue syndrome which fail to respond adequately to parenteral and oral liver therapy combined with suitable dietetic measures, since treatment of these groups of megaloblastic anemia with folic acid is usually required only for a period of a few weeks and the chances of developing neurologic disease are remote.

**Artificial Infection with Ancylostoma Duodenale in Polycythemia.**—Brumpt and Gujar point out that treatments of polycythemia formerly in use have been disappointing. In 1939 they, together with Duvoir of Paris, decided to try artificial infection with Ancylostoma duodenale. A small amount of the stool of a patient infected with Ancylostoma duodenale is mixed with animal carbon in an earthen vessel which is placed in a glass bowl containing water. The eggs mature at the temperature of 25 C. and develop into rhabditiform larvae, which after a series of moultings become strongyloides and later infective strongyloides. The latter after ten days gather in the clean water of the glass bowl. The authors use from 300 to 600 larvae according to the degree of polycythemia and the patient's body weight. To inoculate the patient the larvae are collected on a blotting paper soaked in water, which is applied directly over the skin and is covered with cotton to avoid drying. Treatment with hookworms ("ancylostomatherapy") has several advantages. It is simple, and the reduction in the red blood count is slow, regular and never dangerous. It does not require hospitalization or cessation of daily activities. Moreover, the results of the treatment are lasting, as the duration of the untreated hookworm infection in the human body is five or six years. The hookworm infection stops by itself or is easily checked at any stage. The results have been uniformly satisfactory in the 25 patients treated by the authors.

**Subacute Bacterial Endocarditis.**—Bramwell says that in 1944 the Medical Research Council initiated an investigation of the treatment of subacute bacterial endocarditis with penicillin at twelve research centers in Britain. His department in Manchester participated in this investigation. His paper is based on the first 50 cases of the disease treated there. Bramwell obtained the impression that a favorable response to penicillin may be expected in about half the patients with subacute bacterial endocarditis; it should be possible to improve on that figure by earlier diagnosis. Early diagnosis is often difficult, and it is suggested that in every patient with unexplained pyrexia, especially if there be an associated heart lesion, a blood culture should be taken without delay. The longer the infection is allowed to run on, the greater the damage to the heart, and consequently the greater the risk of heart failure, which is the principal cause of death. There is a second reason why early diagnosis is so important. The preexisting heart lesion is generally trivial and, if only these patients can be brought under treatment before the infection has had time to produce further damage, it may be hoped to render many of them fit to resume their former occupations. Unfortunately, in some cases, a progressive valvular stenosis develops in the course of healing; in fact, the cure of the infection appears to be directly responsible for the aggravation of the valvular lesion. At present we have no means of dealing with this complication, but perhaps surgeons may be able to help. The high incidence of bacterial endocarditis during pregnancy may prove to be a clue to the line of investigation that should be pursued in searching for preventive measures to combat this disease. The discovery of penicillin has opened a new chapter in the story of bacterial endocarditis. There are other chapters waiting to be written.

**Streptomycin in Meningitis due to Hemophilus Influenzae.**—Smythe points out that meningitis due to Hemophilus influenzae is an important cause of suppurative meningitis, particularly in children under the age of 2 years. In the present series 12 patients were admitted in fifteen months. All were transferred, however, from hospitals covering a wide area. One of the 12 cases of H. influenzae meningitis is excluded from evaluation because there was no bacteriologic evidence of active infection on admission. Of the remaining 11 patients 3 died, and in 1 of these the organism became resistant to streptomycin. Streptomycin gave good results in the cases of mild or moderately severe disease but was unsatisfactory in 3 cases of severe disease. In 3 cases a relapse followed a full course of streptomycin. Factors that might predispose to a relapse are discussed, with particular reference to the duration of treatment. In view of the failure of streptomycin in cases of severe disease and of the possible development of resistant strains, it is recommended that all cases should be treated with streptomycin and sulfonamide drugs. If there is any reason to suspect a severe infection, either antiserum or penicillin should be given in addition.

**Caudal Anesthesia for Oliguria in Eclampsia.**—Bloch reports the case of woman, aged 22, who had oliguria in her thirty-sixth week of pregnancy. The case is noteworthy because of the remarkable diuresis which followed continuous caudal anesthesia. The author believes that the immediate mechanism of most of the signs and symptoms of eclampsia is vascular constriction or obstruction. Hingson and his co-workers in 1947 reported rapid control of eclampsia by sympathetic block. Where the sympathetic nerves have to be blocked for any length of time, continuous caudal or continuous spinal anesthesia may be employed, because it has the advantage of being simpler than paravertebral block. The author feels that although he cites only a single case, this form of therapy deserves a trial in similar conditions.

**Fluorine and Endemic Goiter.**—Steyn cites observations which suggest the possible association of harmful quantities of fluorine in the drinking water with the occurrence of goiter and the possibility that the goitrogenic effect of fluorine is aggravated by a high calcium content in the drinking water. Fluorine has a special affinity for the thyroid. Various investigations have shown that appreciable quantities of fluorine fed to animals induce an increase in the size of the thyroids. There is a fluorine-iodine antagonism, and it appears feasible that at least in some areas of endemic goiter excessive quantities of fluorine in the drinking water play a part. When a deficiency of iodine is recognized as the cause of endemic goiter, the deficiency may be endogenous and not exogenous. The medical faculty of the University of Pretoria is at present making arrangements for investigations into the possible relationship of fluorine in the drinking water and the incidence of goiter in the inhabitants of several regions in South Africa. Fluorine is being used against dental caries. It has been suggested that small quantities be administered during pregnancy in order to strengthen the fetal teeth. If this method were to be used there are two dangers to be considered: 1. During pregnancy the demand for iodine is increased and the administration of an antagonist to iodine may precipitate goiter. 2. Iodine plays an important rôle as a lactogenic agent in nursing mothers and the presence of excessive quantities of fluorine in their systems may seriously affect the milk supply. These harmful effects of fluorine could be counteracted by the administration of iodine.

Combat of Tuberculosis in Denmark. R. Linz.—p. 253.
First Results of Treatment with Streptomycin in Sanatorium Practice. A. Gyselen.—p. 264.

**Streptomycin and Pulmonary Tuberculosis.**—Jeanneret points out that general indications for the use of streptomycin in the treatment of tuberculosis have been defined in American, British and more recently French and Swiss reports. These indications are concerned chiefly with episodes of severe hematologic disseminations of primary-secondary tuberculous infection such as in acute miliary tuberculosis, meningitis associated with miliary tuberculosis, apparently isolated tuberculous meningitis and polyserositis. Jeanneret formulates "special" indications for the use of streptomycin in certain chronic or tertiary forms of pulmonary tuberculosis. These indications are based on observations on seventy-seven courses of treatment with streptomycin and on reports of other observers. The author cites special clinical forms in which streptomycin causes considerable improvement: (1) a diffuse bronchopneumonic lesion with small nodular elements, in which the evolution is generally of the subacute type; (2) extensive bronchopneumonic type developing after birth of a child; (3) extensive pneumonic form with recent lobitis; (4) early, diffuse infiltrative form; (5) diffuse nodular form, probably of hematogenic origin, and (6) biapical nodular form of recent development. Streptomycin is likewise valuable in situations created by an accident in the spontaneous evolution of a lesion or by a complication brought on by treatment. This refers to dissemination caused by aspiration of a purulent exudate in cases of pleuropulmonary perforation; exudative pericavitary exacerbation; tuberculous pneumonic exacerbation after thoracoplasty, and atelectasis due to bronchial stenosis. Special indications are suggested for streptomycin treatment in certain localizations of the tuberculous process such as laryngeal and bronchial tuberculosis, pleural complications, tuberculous empyema, urogenital tuberculosis, tuberculous fistulas and osteoarticular tuberculosis.

**Streptomycin in Laryngeal Tuberculosis.**—Derscheid and Toussaint are of the opinion that collapse therapy is the most important weapon against laryngeal tuberculosis. The best way to treat the larynx is to give attention to the lung which infects it. The authors discuss the value of streptomycin on the basis of six case histories. Streptomycin is effective chiefly against the pain of laryngeal tuberculosis, but there is also a rapid and spectacular regression of the inflammatory lesion. The vegetative lesions are less rapidly influenced; ulcerations react if they are recent and associated with a congestive process. Old destructive lesions remain uninfluenced by this treatment. Since tuberculous infection progresses generally from the bronchi to the trachea, from the trachea to the larynx, through submucous ascending lymphangitis, streptomycin should be applied early, when infection is still localized in the trachea or the laryngeal ventricle, the endoscopic laryngeal field still being normal. Diagnosis is made from the clinical symptoms and on the basis of bronchoscopy. The authors obtained their results with limited doses of streptomycin.

Hypocholesterolemia in Chronic Undernourishment. G. Schettler and J. Schmidt-Thomé.—p. 463.
Reduction in Capillary Resistance in Hypertension, and Attempted Treatment with Rutin. H. Hein.—p. 466.
*Latent Hepatic Disturbances and Gastroduodenitis as Causes of Identical Syndromes. E. Strehler.—p. 469.

**Hypertrophy of Heart and Critical Weight of Heart.**—Linzbach says that numerous counts made of the muscular fibers of human hearts, varying in weight between 45 and 1,120 Gm., have demonstrated that the normal human heart has a constant number of fibers. The growth of the fibers takes place harmoniously, the relationship between length and width remaining the same. The increase in the mass of the heart muscle as the result of prolonged increase in the beat performance is interpreted as structural adaptation. The critical limit of the structural adaptation is reached at a weight of 500 Gm. Increase in the weight of the heart below this critical limit is brought about completely by the increase in the volume of the fibers (normal growth and physiologic hypertrophy). The average volume of the fibers is proportional to the weight of the heart. Hearts with weights exceeding the critical weight occasionally show a numerical increase in fibers (hyperplasia) in addition to the hypertrophy. In the majority of cases, the late stages of pathologic hypertrophy, beyond the critical weight of the heart, are accompanied by degeneration of groups of cardiac fibers with induration and a compensatory hypertrophy of the fibers that remained intact. This results in shifting in the structural elements of the cardiac muscle and in an eccentric hypertrophy. Such hearts may prove refractory to the action of digitalis.

**Latent Hepatic Disturbances and Gastroduodenitis.**—Strehler shows that the subjective disturbances in latent hepatopathy greatly resemble those of gastritis and duodenitis. Abdominal symptoms are complicated by impairment of the general condition and by psychoneurotic symptoms. The similarity between the symptomatology of these conditions is explained by the fact that gastroduodenitis may interfere with the proper function of the liver and that disorders of the liver may be accompanied by disturbances in the gastric acidity. The function of the pancreas also is frequently impaired in patients with these disorders. On the basis of 6 case reports the author describes the interrelationship of hepatic, pancreatic and gastric disturbances. This syndrome indicates that the gastrointestinal tract with its adnexae, liver and pancreas, forms a functional unit. The treatment of the disorders involving this functional unit requires the exclusion of noxae that have a damaging effect on stomach and liver, the substitution of the lacking digestive ferments, regulation of fecal elimination, a well balanced diet and the rectification of social, familial and occupational problems.

Determination of Thiamine Deficiency by Examination of Blood: Thiamine Pyrophosphate Content of Erythrocytes and Leukocytes in Healthy Persons and Patients. E. Florijn and G. Smits.—p. 2891.
*Small Doses of Roentgen Rays in Treatment of Carriers of Diphtheria Bacilli. J. T. van der Werff.—p. 2900.
Toxoplasmosis Combined with Situs Inversus Totalis. S. van Creveld, P. Arons and J. I. de Bruyne.—p. 2903.
Acute Cerebral Tremor in Ataxia in Young Children. A. Dekker-Jonker.—p. 2912.

**Roentgen Irradiation for Diphtheria Carriers.**—Van der Werff used this method in the course of the last four years in 110 patients with diphtheria in whom bacilli still persisted three weeks after the acute phase of the disease had taken its course. He uses 200 kilovolts, 6 milliamperes, and 0.5 mm. copper filter and a focus-skin distance of 40 cm. The irradiation is applied first on one side and the following day on the other side. With this treatment 90 per cent of the carriers became negative within two weeks, whereas of the patients not so treated only 30 per cent became negative during this period.

*Tuberculin Reaction with Ordinary Pirquet, Adrenalin-Pirquet and Mantoux Tests. O. M. Andenaes.—p. 1676.
Tuberculin Test According to Trambusti. P. Sallinen.—p. 1682.
Pulmonary Aspergillosis. Å. Nordén.—p. 1683.

**Diagnostic BCG Reaction in Sarcoid of Boeck.**—Danbolt states that the preliminary results of the diagnostic BCG reaction in 19 patients with sarcoïd of Boeck do not support the view that the disease is of tuberculous nature. Many of the positive Mantoux reactions obtained in patients with the disorder must be assumed to be of unspecific kind.

**Tuberculin Reaction with Ordinary Pirquet, Epinephrine-Pirquet and Mantoux Tests.**—Andenaes attributes errors in tuberculin testing to the tuberculin preparation used and to mistakes in measurement and in determination of positive results. His survey indicates that the Pirquet test with highly potent tuberculin and addition of epinephrine is nearly as sensitive as Mantoux with 1 mg. He concludes that BCG vaccination of young persons is allowable after a single negative reaction to an epinephrine-Pirquet test; no complications were reported after some two hundred BCG vaccinations.

*Does Employment of Universal Donors Involve Danger? M. P. Robert, P. H. Bonnel and H. Perrot.—p. 691.

**Dangers From Universal Donors.**—Robert and his associates call attention to the fact that American authors in 1946 demonstrated that when plasma from universal donors has a high agglutinin content, it is likely to cause severe reactions when injected in sufficient quantities (250 cc.). On the basis of their studies the authors conclude that blood transfusion from universal donors introduces into the recipient foreign agglutinins, which are rapidly neutralized, since they are no longer detectable in the vein after a passage of only 20 cm. The agglutinins are fixed by the plasma but also by the erythrocytes, which collect in clumps sometimes of considerable volume. Ordinarily no clinical accident results, but the agglutination is accompanied by a certain amount of hemolysis which is harmful to anemic patients and to those who are weakened and in poor condition. Consequently, in patients of this type it is advisable to employ blood donors of the same group and avoid universal donors with high agglutinin titers.

*Suppurating Lymph Node Complications of BCG Vaccination: Rosenthal Technic. P. Cantonnet Blanch, H. Cantonnet Blanch and A. Perez Seremini.—p. 85.

**BCG Vaccination.**—Cantonnet Blanch and collaborators report 12 cases of suppurating lymph nodes complicating BCG vaccination administered by the Rosenthal technic. The reactions consisted of local, single or multiple abscesses, infarction of lymph nodes with consequent abscess formation and fistulization, and mediastinal, inguinal and supraclavicular abscesses. These different types of abscess formation have a long course and characteristics of a tuberculous abscess. They leave scars like those of tuberculous abscesses. In some cases single or multiple abscesses appear eight or more months after vaccination.

# Book Notices

***The Therapy of the Neuroses and Psychoses: A Socio-Psycho-Biologic Analysis and Resynthesis.*** By Samuel Henry Kraines, M.D., Assistant Clinical Professor in Psychiatry, University of Illinois, College of Medicine, Chicago. Third edition. Cloth. Price, $6.50. Pp. 642, with 6 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

This, the third edition of Kraines' text, is a well bound, clearly printed, impressive tome which, to all external appearances, seems to justify the mathematician Hodgson's delightful dictum in the Hunting of the Snark: "Anything I *tell* you *three times* is true!" A survey of the preface and the table of contents further heightens the reader's expectations, since he learns that sections on "psychiatric geriatrics," prefontal lobotomy, group psychotherapy and epilepsy have been added, and that the material of previous editions (which, as earlier reviews in THE JOURNAL have pointed out, greatly needed revision) has indeed been "thoroughly revised." Unfortunately, as was the case in these previous editions, actual perusal of the text will again tend to misguide the naive reader and to disappoint the informed one. Here are sample excerpts:

Page 26: "Thus, schizophrenia may be said to occur because of constitutional inadequacy"—a highly dubious assertion but made here almost without qualification.

Page 29: "Psychoneurotic symptoms are better described individually by the terms tension, or symbolism or their combination rather than by attempting to group them arbitrarily"—a statement that achieves meaning only when translated freely and charitably. But charity comes hard when the reader learns further (p. 30), "The symptoms presented by the patients suffering from psychoneuroses may be those of a state of general 'psychological' tension or of focal tension (stretched, overly active) of the autonomic nervous and other related systems."

Page 176 offers a typical sortie into empty polemics: "While it appears quite clear to the author, that environmental forces are the essential molding forces of each particular constitution, the psychoanalysts on the other hand insist that there are 'deeper' reasons for adult neuroses."

Again, on page 107, in explaining "the technique of changing attitudes," Kraines' pen seems to have been guided by the shade of Coué: "The patient was to say to herself, 'those old attitudes were immature; I shall try to feel and act according to these new attitudes.'"

On page 490, Kraines begins the most dangerously misleading section in the book by stating, "The contraindications to convulsive shock therapy are few indeed . . . (p. 502), the same shock treatments may be given in selected cases in the office [and] the physician can give the treatment alone [*sic*]." Finally, page 578 introduces perhaps the most inaccurate and garbled "exposition" of psychoanalysis since Joseph Jastrow.

It would not be fair to Kraines to conclude from these quotations and comments that his entire text is an arid waste, difficult to plow with furrowed brow and woefully infertile in yield. On the contrary, there are sections that reflect Kraines' undoubted experience and his sincere attempts to communicate his clinical intuitions. Even in these, however, his verbiage, as may be seen in the samples quoted, is so inexact and his reasoning so often slipshod that the reader cannot help but agree with the semanticist Witgenstein that unclear expression bespeaks hazy observation and unscientific interpretation. With such major defects, it seems unnecessary to add that the volume as a whole is padded, repetitive, poorly organized and almost devoid of documentation. Perhaps, however, those of us who have become a bit discouraged while waiting for a text that will do justice to modern clinical psychiatry can take heart from yet another one of Kraines' gems of dialectic (p. 3): "Probably the most important element in therapy, becoming more evident as one seeks the similarities among the differences, is the sustaining, driving, curative therapy of hope. . . ."

**Dictators and Disciples from Caesar to Stalin: A Psychoanalytic Interpretation of History.** By Gustav Bychowski, M.D. Preface by Carl Binger, M.D. Cloth. Price, $4.25. Pp. 264. International Universities Press, 227 W. 13th St., New York 11, 1948.

In this book Bychowski attempts to interpret the life and times of Julius Caesar, Oliver Cromwell, Robespierre, Hitler and Stalin according to what the author considers psychoanalytic "insight." The theme of the work is sounded almost immediately (p. 12) as follows:

"The course of Roman history can serve as a perfect illustration of Freud's theory expounded *in Totem and Taboo,* according to which the earliest form of society was marked by a struggle between the primal father of the horde and his sons who banded together in order to overthrow him and divide the females among themselves. Thus, about 1900 years before Freud pointed out this pattern, the Roman king was killed, the Republic was established and its path of development was apparently bound for democracy. However, the collective mind still cherished deep longing for the guiding and ruling parent. In a period of misery and social upheaval, the vortex produced Caesar . . ."

This monothetic approach not only to biography, but to economics, culture and politics, is repeated monotonously throughout the volume. Wherever possible, selected facts about the childhood of each of the dictators are mustered and "interpreted" to support Bychowski's thesis; whenever such facts are unavailable we are treated to priceless examples of bland presumption like the following:

"Knowing nothing of the basic conflicts of [Oliver Cromwell's] childhood days we can at best imagine them. In a boy of a violent disposition, nurtured in an atmosphere of puritan constraint and austerity, processes of forcible and yet insufficient repression of the oedipus complex must have undoubtedly occurred. Such forceful repression of 'wicked' tendencies left behind a visible trace in the shape of a sense of sinfulness and guilt, as well as a recurring fear of death. The latter is undoubtedly linked up with the impulses of pansexualism. The youthful 'sinner' seems to have reached out for salvation . . ."

These are samples enough of a type of psychoanalytic flounderings in biography and history which were popular for a time after the publication of Freud's quasisociologic writings two generations ago; today most psychoanalysts have discarded the naiveté of earlier formulations and have come to appreciate, along with their fellow social scientists, the almost incredible complexity of the determinants of human history. Dr. Bychowski's book is therefore recommended only to those who are still interested in a narrowly cultist approach to this field.

**Sexual Endocrinology of Non-Mammalian Vertebrates.** By L. H. Bretschneider and J. J. Duyvené de Wit in collaboration with Dudok de Wit and others. Monographs on the Progress of Research in Holland During the War. Editorial Board: R. Houwink and J. A. A. Ketelaar. Paper. Price, $2.75. Pp. 146, with 96 illustrations. Elsevier Publishing Co., Inc., 215 Fourth Ave., New York 3, 1947.

Chapter 1 records the effects of various substances added to the water of the aquarium on the growth of the ovipositor tube of a small fish, the bitterling. Various substances give characteristic curves when onset and rate of growth are plotted against time, and the test can be made quantitative. Steroid hormones have especially low thresholds; 4 to 6 micrograms of progesterone, for example, produce measurable growth in less than five hours. Extracts of human corpora lutea gave curves resembling those of pure progesterone. Unfortunately, the only basis for seriating them was the clinical history. Four which were removed during menstruation gave as high values as the average of all cases in which the results were positive. A pair of ovaries from a full term infant showed as much progesterone per gram of tissue by this test as any of the corpora lutea. The test cannot be used for the diagnosis of pregnancy, since urine from some nonpregnant women gave as high values as those from the pregnant.

Chapter 2 deals with the histophysiology and comparative anatomy of the hypophysis and hypothalamus. The conclusion is drawn that the hypophysis activates the ovary and that atretic follicles secrete the hormone which induces growth in the ovipositor because (*a*) extracts of fish hypophysis injected during the sexually inactive time of year bring about an increase in the number of atretic follicles and also ovipositor growth; (*b*) during the breeding season the number of atretic as well as normal follicles reaches a maximum, and (*c*) after ovariectomy the steroid hormones do not stimulate the ovipositor. It is stated that they do not act directly on the ovaries but operate through the hypophysis. This is apparently based on a single successful total hypophysectomy. The length of time that this fish survived the operation is not stated.

Chapter 3 gives an account of oogenesis and of follicular atresia in the bitterling. On the assumption that the atretic rather than the normal follicules produce the ovipositor-stimulating hormone, there is an extensive discussion of the "preovulatory" and the "postovulatory" corpus luteum in the various groups of vertebrates.

Chapter 4 presents data on the reproductive physiology of the bitterling, of two species of viviparous fishes and of the common toad.

**The Treatment of Rheumatism in General Practice.** By W. S. C. Copeman, O.B.E., M.A., M.D., Physician in Charge, Department of Chronic Rheumatic Diseases, West London Hospital, London. Fourth edition. Cloth. Price, $4. Pp. 264. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

In his preface, the author states that this book is written for the benefit of the general practitioner. Many subjects are covered under the title of acute and chronic rheumatism which cannot be called rheumatic, such as chorea, sciatica, neuritis and gout. However, the discussion of these subjects has some merit in a small volume if the reader does not assume that sciatica is a disease. In general the book should be considered as an adjunct to a lot of other published knowledge.

There are some statements with which the reviewer does not agree; for example, he does not agree that growing pains are one of the first signs of rheumatism in a child. If this were the case, the United States would have a large population of children with endocarditis. It would also seem far afield from rheumatism to call "frozen shoulder" and subacromial bursitis fibrositis. Usually the frozen shoulder is a result of "bursitis" of the subacromial bursa. A great many doctors believe, however, that tendonitis of the suprascapular tendon is the source of such lesions.

A good deal of the therapy described in the book is based on many drugs which are probably not very useful in curing the disease. The section on diet and physical therapy is too sketchy, and the reviewer cannot agree that putting an arthritic joint through its full range of motion is sound therapy.

On the whole, there is much in this book which is of value to the profession in general.

**Roentgen Studies of the Lungs and Heart: A Series of Lectures Delivered at the Center for Continuation Study, University of Minnesota.** By Nils Westermark, M.D., Director, Department of Radiology, St. Göran's Hospital, Stockholm, Sweden. Edited by Leo G. Rigler, M.D., Professor of Radiology, University of Minnesota. Cloth. Price, $7. Pp. 216, with 98 illustrations. University of Minnesota Press, Minneapolis 14; Oxford University Press, Amen House, Warwick Sq., London E.C. 4, 1948.

As the editor states in his introduction, "such a series of original papers does not exhibit a systematic or well rounded presentation of the roentgen diagnosis of diseases of the thorax, nor is any such presentation intended. Rather this is a series of loosely connected studies united chiefly by the manner in which the author interprets his findings in the light of the physiology and pathology of the respiratory and circulatory systems."

The author discusses in detail the various technics which he employs. Emphasis is placed on fluoroscopy, for study of the respiratory movements, observation of the effect of varying intrathoracic pressures and the selection of the projections in which the roentgenograms are to be made. In Sweden roentgenograms are always made under fluoroscopic control. To insure comparable films the same intrabronchial pressure is used for all examinations. To obtain this a water manometer is connected to the patient's mouth. If necessary roentgenograms are also made in different phases and with different intrabronchical pressures. The value of the roentgenograms made with different intrabronchial and intra-alveolar pressures depends on the effect on heart size and the filling of the pulmonary vessels. The author has subjected a series of 15,000 patients to examinations under both normal and high intra-alveolar pressures. He finds that there is a definite difference evident in pulmonary stasis, pulmonary edema and acute pneumonic changes. There is little or no change in chronic inflammatory disease or in tuberculosis.

There are chapters on the roentgen diagnosis of pulmonary emphysema, bronchial tuberculosis, primary tumors of the lung and pulmonary embolism. There is a comprehensive table and series of diagrams listing the various diagnostic features in bronchostenosis and their changes with the progress of the disease, which he divides into four stages. In stage I the affected lung area shows a decreased radiability on inspiration; in stage II the area will appear normal on inspiration but will appear relatively emphysematous on expiration; in stage III emphysema is evident in both phases, while only in stage IV does the atelectasis become evident.

In the final chapter there is a discussion of the mechanics of circulation and the author's experimental methods of simultaneous roentgen cinematography and electocardiography. These studies were performed by injecting colloidal thorium dioxide (thorotrast®) into the circulatory system of rabbits. His concept of the filling and emptying of the cardiac chambers is not in complete agreement with the opinion generally held. However, the method of study is new, and possibly more accurate than previous approaches.

**Die Lungentuberkulose beim Erwachsenen: Klinik und Therapie für die Praxis.** Von Dr. Hermann Weber. Second and third editions. Fabrikoid. Pp. 417, with 259 illustrations. Grune & Stratton, 381 Fourth Ave., New York 16; Wilhelm Maudrich, Spitalgasse 1 B, Vienna IX/2, 1948.

Under clinical examination are good presentations of the patient's history and the conventional physical examination. Other phases of the examination are included, such as various methods of searching for tubercle bacilli, including cultural methods and animal inoculation. Several pages are devoted to the study of the patient's blood with reference to sedimentation rate, complement fixation reaction and methods of searching for tubercle bacilli in the blood.

The evolution of tuberculosis in the human body is discussed in its various phases, from the development of the primary complex to its most advanced and destructive phases, including both acute and chronic forms. An especially good chapter is devoted to nontuberculous pulmonary conditions, including cancer, syphilis, tularemia, psittacosis, bronchiectasis, cystic disease and sarcoidosis. Four pages are devoted to allergy in tuberculosis.

The second section of this book includes treatment. Various preparations, such as calcium, copper, gold, tuberculin, sulfonamide compounds and penicillin, are discussed, but no mention is made of the sulfones or streptomycin. The numerous attempts to immunize against tuberculosis by such workers as Koch, Friedmann and Calmette are included.

Under collapse therapy over 25 pages are given to artificial pneumothorax. Various other collapse procedures are discussed at considerable length, such as pneumonolysis, extrapleural pneumothorax, oleothorax, phrenemphraxis and thoracoplasty. Physicians devoting themselves to chest diseases will find much valuable information in this book.

**Handbuch der Therapie: Therapie des praktischen Arztes in Einzeldarstellungen.** Herausgegeben von Prof. Dr. T. Gordonoff. Lieferung I: Vitamine und Vitamin-therapie. Bearbeitet von Prof. Dr. med. Emil Abderhalden und Prof. Dr. med. Georges Mouriquand, Direktor der Kinderklinik (Hôpital Edouard Herriot) der Universität Lyon, Lyon. Paper. Price, 28 Swiss francs. Pp. 408, with 44 illustrations. Hans Huber, Marktgasse 9, Bern, 16, 1948.

The book is divided in two sections. The first, "Experimental Vitamin Studies," comprising 188 pages, is written by Abderhalden. The theoretic discussion is well written and well documented. The author has had access to American as well as European literature. This section includes not only discussion of each of the established vitamins, but also of the essential amino acids and fatty acids. The 44 illustrations include many clinical cases of vitamin deficiency.

Section II, "Therapy of Hypo- and Avitaminoses," is written by Mouriquand. This section was written for the practical guidance of the physician. It is not illustrated and has no bibliography, though investigators often are referred to by name. The etiology of the given avitaminoses, the effect of other disease entities on the requirement for the given vitamin, the type of vitamin preparations available and the dosage of each are discussed in detail. Each of the chapters on thiamine, ascorbic acid and vitamins A and D covers more than 30 pages. This section is interesting particularly as a means of comparing European and American thinking as well as therapy in diseases involving vitamin metabolism.

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## ANTICOAGULANTS AND PROTAMINE INSULIN

*To the Editor:*—Are there contraindications to the use of anticoagulants for thromboembolic disease in diabetics? Physicians state that heparin is not effective or is contraindicated because of the neutralizing effect of protamine zinc insulin. Does protamine zinc insulin given subcutaneously have the same neutralizing qualities on heparin as protamine sulfate given intravenously? Does heparin alter the subcutaneous deposit of protamine zinc insulin so as to influence insulin utilization?

Peter C. Posatko, M.D., Plains, Pa.

ANSWER.—Both heparin and "dicumarol" may be used in diabetic persons if the same care is observed in the selection of patients as with nondiabetic persons and if the same caution is used in the administration of the drugs together with appropriate laboratory studies.

Evidence is not available to indicate that heparin is not effective or is contraindicated in a patient receiving protamine zinc insulin. One authority states that most observers who have worked with protamine as an antidote for heparin believe that it is effective approximately milligram for milligram. Since protamine zinc insulin provides only 1.25 mg. of protamine per hundred units, the amount of heparin neutralized would not be significant in comparison with the total amount of heparin usually administered. It would appear unlikely that protamine zinc insulin given subcutaneously would have the same neutralizing effect on heparin as protamine sulfate given intravenously.

No accurate information is available to indicate whether or not the administration of heparin alters the effectiveness of protamine zinc insulin given subcutaneously. It is doubtful, however, that in actual practice heparin would influence the insulin effect to any significant degree.

## BURNING OF THE LIPS

*To the Editor:*—A 63 year old white woman complains of burning and dryness of the lips and extreme nervousness. Physical examination shows considerable dryness of the lining of the lips with several areas suggesting small petechial hemorrhages with a suggestion of formation of bullae. Once during a period of four months' observation she had a shower of petechiae all over the body. Investigation at that time showed normal platelet count, bleeding time, coagulation time, hematocrit reading and complete blood cell count. She responded to a course of "rutorbin" (rutin and ascorbic acid in proportion 1:5). However, the lip findings have not changed. She has been treated with prolonged high vitamin B dosage both parenterally and orally and nicotinamide without symptomatic relief. The antihistaminic drugs have been tried both orally and locally without benefit. Allergy diets have also been used without benefit. There are some definite neurotic trends in this patient, and she probably has a mild psychoneurosis. However, the fixation of complaints of the lips is puzzling. Please suggest diagnosis and treatment.

M.D., Texas.

ANSWER.—From the description given, the main complaint of this patient seems to be the burning of the lips. One would think of a psychogenic basis for her complaint. The burning of the lips probably corresponds to the more frequently seen burning of the tongue, commonly called glossodynia. As stated by Sulzberger and Zaidens (*M. Clin. North America,* 32:669-685 [May] 1948), these patients often suffer from cancerophobia. For some unknown reason, this condition occurs most frequently in women, and usually about the time of menopause.

Alvarez (*Postgrad. Med.* 4:96-101 [Aug.] 1948) believes that burning in the mouth without any local symptoms is sometimes due to a little stroke. This symptom is commonly seen in the cases of women around the age of 50.

The petechiae seen at one time probably are part of a general petechial eruption. These changes do not seem to bear any relationship to the burning, except that the dryness may have been a factor in localizing her complaints. A consultation with a dermatologist might be indicated to exclude the possibility that this woman is suffering from some specific dermatologic condition such as lichen planus of the lip.

Therapeutically, these patients are a difficult problem. One should investigate the psychologic factors. General supportive measures, iron, liver extract and vitamins are often prescribed, but are usually not of particular help. This patient probably will need consultation with a psychiatrist.

## PARALYSIS FOLLOWING TETANUS ANTITOXIN

*To the Editor:*—During May 1948 a young, white American farmer, aged 27 years, requested antitoxin against tetanus. A few days before he had stepped on a nail in the barnyard. His foot was somewhat painful and tender to touch. Examination revealed a small tender area at the point of entrance of the nail. Tetanus antitoxin, 1,500 units, was given. In about fifteen minutes a severe case of pruritus and hives developed. Ephinephrine was given hypodermically and tripelennamine hydrochloride, 50 mg., prescribed for four doses daily for a week. At the end of one week neuritis of the right arm and forearm developed. Tripelennamine hydrochloride in the same dosage as before controlled the symptoms. About six weeks after the injection of tetanus antitoxin a distinct flaccid paralysis of the right biceps muscle with cutaneous sensory changes of the forearm occurred. The injection did not hit the nerve, I am sure, as it was not given in the area of the nerve. Four months later there is a distinct paralysis of the right musculocutaneous nerve. The biceps muscle is flaccid and useless. It is about ¾ inch (1.9 cm.) smaller in diameter than the opposite biceps when measured with the elbow extended. A search of the literature does not reveal any similar cases. At present the patient is receiving a high vitamin diet with instructions not to use the arm too much in heavy lifting as it is feared that the injured muscle might be made worse. Will full recovery occur?

M.D., California.

ANSWER.—A uniform type of paralysis of the upper extremities, usually confined to the right, and frequently involving only muscles of one shoulder, was described in this country by Ayer in 1935 (*J. Nerv. & Ment. Dis.* 81:676-682 [June] 1935). He reported 5 cases of paralysis following antitetanus serum seen within a period of one year. Analysis of the literature at that time yielded 40 reports of cases, mostly from France. Ayer's patients presented a similar picture, the paralysis coming on suddenly or rapidly during or just after the height of serum sickness, preceded by excruciating pain involving more nerves than were subsequently paralyzed. The paralysis, either mild or complete, followed root distribution but was most conspicuous in the muscles supplied by the fifth cervical root, principally the deltoid and biceps. The amount of protein in the cerebrospinal fluid was above normal in 1 case.

The site of the paralysis was not clearly related to the place of injection. In Ayer's series 1 patient had the serum injected under the left breast, but experienced paralysis in the right arm; another had paralysis of the right arm after injection in the buttocks. In the 3 other patients, however, paralysis developed in the arm receiving the injection.

The paralyzed muscles showed a partial reaction of degeneration. Atrophy and paralysis were often marked in contradistinction to the almost normal electrical changes. Sensory symptoms were minimal, except for the explosive initial attack of pain. The prognosis was considered uniformly good for complete restoration of function.

Bennett added 5 more cases in 1939 (THE JOURNAL 112:590-596 [Feb. 18] 1939) and gave a thorough review of the literature, pointing out that the first accurate case report was made by Gangolphe in 1908 in France (*Lyon méd.* 110:497-499, 1908), while Richardson reported the first American case in 1917 (THE JOURNAL 68:1611-1612 [June 2] 1917). Bennett's paper contained illustrations showing the atrophy. An excellent general review of the neurologic complications following the administration of vaccines and serums in general was given by Robinson in 1937 (*New England J. Med.* 216:831-837 [May 13] 1937).

The condition was briefly described by Osler, under serum sickness and neurologic symptoms after tetanus antitoxin, as follows:

> "More disturbing are the severe neurological disturbances that occasionally ensue to persist for several months and then, as a rule, clear up. Paresis or paralysis in the distribution, unilaterally, or bilaterally, of the brachial plexus is particularly frequent, but disturbance in other peripheral nerve groups occurs."

## COBRA VENOM FOR RHEUMATOID ARTHRITIS

*To the Editor:*—What is the consensus relative to the use of cobra venom in treatment of rheumatoid arthritis? Is this treatment contraindicated when gold injections are given for this type of arthritis?

M.D., New York.

ANSWER.—Talkov and Bauer (*New England J. Med.* 228:152-154 [Feb. 4] 1943) concluded "that cobra venom is of no value for the relief of pain associated with rheumatoid arthritis." Previous reports of varying degrees of benefits were said to have been based on observations of small groups of patients and on reports lacking in sufficient detail to allow critical evaluation of results. The present consensus of most rheumatologists is that preparations of cobra venom are of doubtful value or of no value in the treatment of rheumatoid arthritis. However, to answer the inquirer, there would appear to be no pharmacologic contraindication to the concomitant use of this substance and gold salts in the treatment of this disease.

## RABIES PROPHYLAXIS

*To the Editor:*—In the October 30, 1943 issue of The Journal an article on the prophylaxis of rabies concluded, from experimental evidence, that 20 per cent soap solution or even tincture of iodine was superior to fuming nitric acid. Is this sufficiently well accepted so that we may use it instead of the time-honored nitric acid? M.D., Massachusetts.

ANSWER.—The literature does not indicate that nitric acid is no longer used exclusively in cleansing human wounds from dog bites. The Illinois Department of Public Health, where the work described in the article was done, recently recommended (*Chicago M. Soc. Bull.* 50:102 [Aug. 16] 1947) that "the wound be cleansed immediately and thoroughly washed with soap and water. Cauterization of the wound with nitric acid should then be carried out by a physician." Thorough cleansing of the wound with soap, preferably green soap, and water is however always urged, before any local antiseptic or caustic is applied. The article deals only with experimental rabies (Shaughnessy, H. J., and Zichis, J.: Prevention of Experimental Rabies, J. A. M. A. 123:528 [Oct. 30] 1943). Because we have no practical method of determining whether the virus of rabies is present in a human wound, it cannot be determined which method is most effective in cleansing such wounds of rabies virus.

## DISTANT METASTASES OF CANCER OF THE CERVIX

*To the Editor:*—Does carcinoma of the cervix metastasize to the breast? How often does this occur? Frederick Falkson, M.D., Walden, N. Y.

ANSWER.—Distant metastases from squamous cell carcinoma of the cervix are being more frequently reported since these tumors have been treated with irradiation. The reason for this is that the primary lesion is held under control so that the patient lives long enough for the metastases to occur. Metastases to cervical nodes seem to be more frequent. However, they are often reported in the axillary nodes, brain, lung and osseous system. Extension could occur in the breast, though these incidences are rare.

## STERILITY AND HORMONE DEFICIENCY

*To the Editor:*—What gland extract will assist a young woman in becoming pregnant? MD., Pennsylvania.

ANSWER.—There is no simple "gland extract" which will assist a woman to become pregnant. A complete examination must be made to determine whether or not there is any glandular deficiency, and, if there is, one or more glandular products may be prescribed. It must be remembered that when there is a gland deficiency, it is not always easy to correct it. If, however, there is a lack of thyroid, replacement therapy usually helps.

## EPILEPSY AND ALCOHOL

*To the Editor:*—A man aged 26 with grand mal epilepsy who has been well controlled for the past two years with diphenylhydantoin sodium has recently been given an automotive driver's license after electroencephalograms. May he now take an occasional social cocktail or two?

Willis P. Baker, M.D., Santa Ana, Calif.

ANSWER.—In general, alcohol and epilepsy do not mix, and the epileptic person who maintains complete abstinence is well advised. In particular, "a cocktail or two" probably would not reverse the good two year record of this patient who continues to take diphenylhydantoin sodium, but he should undertake the experiment at his own risk.

## COLD VACCINES IN CHILDREN

*To the Editor:*—Is the use of prophylactic immunizing injections justified in infants aged 2 or younger for recurrent "colds" or recurrent pneumonia?

M.D., New York.

ANSWER.—"Cold" vaccines and mixed respiratory vaccines are of doubtful value. No known immunization will protect against the etiologic virus of "colds." Their main function is to protect against or reduce the secondary complications due to secondary bacterial invaders. As far as known these vaccines are relatively harmless, and so are worth a trial in the infants over 1 year old that are susceptible to colds. One season's trial should convince the investigator as to their value in an individual patient. It is assumed that other causes of so-called "colds" such as allergens or enlarged adenoids have been eliminated.

The use of the vaccines intradermally is an advantage, as smaller doses are required. Most of the better known pharmaceutical firms make a mixed respiratory vaccine containing streptococci, staphylococci, pneumococci and influenza. It can be started in 0.1 cc. dose and increased 0.1 cc. a week up to 0.3 cc. or 0.5 cc. It should then be given every two or three weeks from September to May. Some children seem to be benefited, while many are not improved.

## BRUCELLOSIS

*To the Editor:*—In the Journal, July 31, 1948 page 1271, a query was published on the diagnosis and treatment of brucellosis. The following comment expresses the unanimous opinion of a group of persons interested in human brucellosis. The answer given in The Journal is misleading. One experienced in the diagnosis of this disease will not question the introductory statement, "The most reliable criteria for the diagnosis of undulant fever are history of patient, clinical symptoms and signs, a positive agglutination test and a positive blood culture," but the implication in the two succeeding statements is misleading, that if agglutinins are absent and the blood cultures are sterile one may depend on the symptoms and a positive reaction to an intradermal test for a diagnosis. Unfortunately, the loose criteria of a vague symptom complex and positive reactions to intradermal tests are being widely employed in the diagnosis of chronic brucellosis. Yet the enthusiasts for skin testing will caution the clinician by stating that the Brucella skin test has no more significance than the tuberculin test as an indication of active disease. This leaves the clinician confused. The skin test is the most abused procedure in the diagnosis of brucellosis. The agglutination test is more dependable when appropriate antigen is used and careful technics employed. Contrary to what is stated in the literature, it is the unusual case of chronic brucellosis in which a blood culture is positive and agglutinins negative. In arriving at a correct diagnosis of brucellosis several factors should be kept in mind: (1) history of exposure to the disease, either directly or indirectly; (2) the association of fever, no matter how low grade, with a vague illness of weakness, aches and pains, sweats and nervousness; the temperature should be taken several times a day; it is unusual to have a bacteriologic proved case with symptoms and have the patient afebrile; (3) a normal or reduced leukocyte count with relative lymphocytosis; (4) the presence of agglutinins, preferably in a titer of 1 to 100 or higher; it is unusual to have demonstrable bacteremia in a case of chronic brucellosis with a lower titer of agglutinins; (5) finally, one should carry out properly conducted cultures of venous blood, recognizing that the absolute diagnosis of brucellosis will have to be made frequently with only the aid of the first three factors. It is doubtful whether enough dependable information accrues from the use of Brucella antigens for skin testing. The patient with acute disease and the seriously ill patient with chronic disease may have negative reactions. The opsonocytophagic test and the skin test are two unreliable procedures for the diagnosis of the sporadic case of brucellosis.

Concerning treatment, the question was not answered with respect to use of para-aminobenzoic acid. This drug is not effective in the therapy of brucellosis. Promising results have been obtained with a combination of streptomycin and sulfadiazine, but such therapy should be reserved for proved cases of brucellosis because both agents may provoke toxic reactions. It is stated in the answer that another form of treatment is the oral administration of sulfadiazine and the intravenous use of human whole blood or plasma. Transfusions of whole blood or plasma should not be taken too lightly. Besides the dangers of reactions, there is the decided risk of transmitting homologous serum hepatitis with either whole blood or plasma. Hepatitis is a much more serious disease than ill defined chronic brucellosis. Wesley W. Spink, M.D., Minneapolis.

## ALLERGY AND MYOPIA

*To the Editor:*—Your answer to the "Allergy and Myopia" in The Journal, September 11 requires some correction and clarification. The answer to the question, "What are the best areas in California for patients with hay fever?" is especially misleading.

True, California is free from the Eastern varieties of ragweed, giant ragweed (Ambrosia trifida) and short ragweed (Ambrosia elatior), but patients sensitive to these will not "almost certainly be free of symptoms in any part of that state." California has the Western ragweed (Ambrosia psilotachya), the bur ragweed (Franseria acanthicarpa) and the slender ragweed (Franseria tenuifolia), all of which are abundant. From observation of hundreds of patients, many of whom are newly arrived from the East, we have noted that patients sensitive to the Eastern variety of ragweed are sensitive as well to the Western variety. By a series of passive transfer exhaustion studies we have proved to our own satisfaction that there is an antigenic relationship between these ragweeds, mainly between the Ambrosia psilotachya and the trifida and elatior. Our unpublished data recently have been verified by Wodehouse (Wodehouse, Roger P.: Patterns of Allergic Sensitization, *Ann. Allergy* 6:358 [July-August] 1948).

In addition, an allergic person, fundamentally, is one who by heredity and other unknown constitutional factors is prone to the development of sensitivity and subsequent allergic symptoms. By moving from one part of the country to another, he certainly does not lose his unusual predisposition. In the case of moving from the East coast to Southern California for his sensitivity to plants with short, sharply limited pollinating seasons he will probably substitute an allergy to plants with prolonged season of pollination. The grass-and-weed-sensitive patient from Chicago or New York on moving to Los Angeles will probably in time have symptoms lasting continuously from February through November, rather than the comparative short episodes of symptoms in the summer and fall.

# DISCONTINUOUS THERAPY WITH PENICILLIN

RALPH TOMPSETT, M.D.
ALPHONSE TIMPANELLI, M.D.
OSCAR GOLDSTEIN, M.D.
and
WALSH McDERMOTT, M.D.
New York

Virtually all of the clinical experience with penicillin has been obtained with dosage schedules which provide what is generally referred to as "continuous therapy." Continuous therapy has come to mean the maintenance at all times of drug concentrations in the patient's blood equal to or greater than the concentration which inhibits growth of the infecting organism in vitro. The commonest method of providing continuous treatment utilizes frequent doses of penicillin administered at short intervals. The other commonly used method employs forms of penicillin which are slowly absorbed from the site of injection. Both of these types of dosage schedule are relatively simple and practicable. Each has certain disadvantages, although these disadvantages have not been considered of importance in view of the therapeutic effectiveness of the drug.

Despite the fact that continuous treatment with penicillin is obviously highly effective, there is no proof that it is necessarily the most desirable or the most practicable form of therapy. Since all of the conventional dosage schedules now employed are based on the concept that continuous treatment is optimal treatment, it has been of interest to review the basis for this concept. Only a brief summary need be presented here, since a complete review of the evidence for and against the validity of this concept has recently been published by Marshall.[1]

Prior to the development of the sulfonamide drugs, the few effective agents available for chemotherapy of infections—for example, the arsenical drugs and quinine—were commonly administered at relatively infrequent intervals. With the sulfonamide drugs, the concept arose that in the treatment of a given infection there exists a particular concentration of drug which may be called the "therapeutic level." Lower concentrations than this were considered less effective and higher concentrations no more effective. Whether or not this concept is valid for the sulfonamide drugs, it has been useful in the administration of the different sulfonamide drugs, which vary considerably in absorption, degrees of acetylation and toxicity. The application of these same principles to the use of penicillin was undoubtedly due, in part, to the general acceptance of these principles as fundamentally sound and independent of differences in potency, toxicity and mode of action among different drugs. Another important influence has been that the measurement of penicillin in the blood has constituted the only rapid means of evaluating different dosage schedules and dosage forms. Although this method has been extremely valuable, its widespread use has tended to attach to the levels themselves a certain intrinsic significance which appears unwarranted.

It is apparent, however, from a review of several early reports on the use of penicillin that some investigators were clearly of the opinion that continuous treatment was not necessary, although they used it for economic reasons, which at that time were of prime importance. Moreover, there are reports of several experimental studies and a few clinical reports to support this opinion. Of particular interest are the studies of the treatment of infections in experimental animals reported by Jawetz[2], White, Lee and Alverson[3], and Zubrod.[4] At least six clinical reports contribute additional evidence.[5] In an extensive and carefully documented study reported in 1944, Tillett and his associates[5a] concluded that satisfactory therapy in pneumoccoccic pneumonia was attained with doses of 10,000 to 25,000 units four times a day. They pointed out that intervals of twelve to sixteen hours could elapse between doses without altering the favorable results. In a study of the oral use of penicillin in pneumonia, Bunn and his associates[5b] omitted the doses of penicillin at night in some patients as soon as it became apparent that defervescence was occurring.

From these and other observations, it appeared that the conventional dosage schedules of penicillin, although therapeutically effective, were based largely on an unproved assumption. Moreover, the problems created several years ago by limited supply and high cost of penicillin are now either nonexistent or becoming

increasingly less important. It seemed of interest, therefore, to investigate further the effectiveness of discontinuous penicillin therapy, employing relatively large doses of sodium penicillin G in aqueous solution administered at intervals of twelve to twenty-four hours. The present report is a summary of the clinical experience thus far obtained with this treatment regimen.

PENICILLIN IN SERUM AVERAGE DURATION OF MEASURABLE LEVELS

Fig. 1.—Routine schedule with discontinuous penicillin therapy.

The study has been conducted on the Cornell-New York Hospital Medical Service and the Cornell Division of Bellevue Hospital. One part of the study has been limited to a comparison of the clinical results obtained with continuous and discontinuous therapy in a single disease, uncomplicated pneumoccic pneumonia. The other has been an attempt to determine the practicability of a regimen of discontinuous penicillin therapy as a routine for the treatment of a variety of infections, exclusive of those already known to require unusually large doses of penicillin.

## DOSAGE SCHEDULES

In figure 1 may be seen a schematic outline of the dosage schedule which was arbitrarily chosen for discontinuous therapy and which has been used throughout this study. Each dose of penicillin consisted of *300,000 units of crystalline sodium penicillin G in* 1.0 cc. of isotonic sodium chloride solution, administered by intramuscular injection. On the first day of treatment, the patient received two doses of penicillin twelve hours apart. Twelve hours after the second dose, the third dose was given, and from that time to the completion of treatment, the patient received only one daily dose of 300,000 units. As indicated in figure 2, after a single dose of 300,000 units, measurable concentrations of penicillin were present in the patient's serum, on the average, for five hours.

The continuous treatment regimen consisted of a single daily dose of 300,000 units of procaine penicillin in oil,[6] which in a previous study conducted in this clinic[7] was shown to provide continuous low concentrations of penicillin in the blood for twenty-four hours, with more regularity than other dosage forms available at the time. In figure 2 may be seen a comparison of the serum concentrations of penicillin obtained during a twenty-four hour period with these two treatment schedules. As indicated in figure 2, after a dose of 300,000 units in aqueous solution, a high peak is reached within a few minutes. The concentration then falls rapidly and on the average is measurable for five hours.[8] Concentrations sufficient to inhibit pneumococci in vitro are present longer than five hours, but in all likelihood are not maintained as long as eight hours following a single dose of 300,000 units.

The lower solid line in figure 2 illustrates the median penicillin concentrations in the serum as determined in 33 patients after a single 300,000 unit dose of procaine penicillin in oil. As may be seen, the concentrations throughout the twenty-four hour period were relatively constant. Of interest also was the fact that in individual patients decided fluctuations from one time to another were seldom observed.

## TREATMENT OF PNEUMOCOCCIC PNEUMONIA

Each of the treatment regimens previously described was established as the routine for the treatment of pneumococcic pneumonia on one medical ward. Treatment was initiated with this routine in all patients in whom the observations at the time of the original examination made it seem likely that they had uncomplicated pneumococcic pneumonia. During the period of the study, 39 patients received discontinuous therapy, and of these 19 had the characteristic observations of *pneumococcic pneumonia, as determined by* clinical, roentgenographic and bacteriologic examinations. In the same period, 32 patients received continuous treatment, and, of these 21 proved to have pneumococcic pneumonia. For comparison of the clinical results obtained with the two dosage schedules in a disease of reasonably predictable course, the patients with proved pneumococcic pneumonia may be considered as a group and the remainder of the cases discussed later.

Of 19 patients who received aqueous penicillin, 12 were over 50 years of age and 5 were over 70. The oldest patients were 81 and 82. Of those who received procaine penicillin, fewer happened to be in the older age groups, although the average age was 59, as compared with 56 in the other group. Only 2 of the first group had positive blood cultures, as compared with 6 in the second group. Many of the patients had, in addition to the acute infection, some chronic disease which could have compromised their chances for recovery.

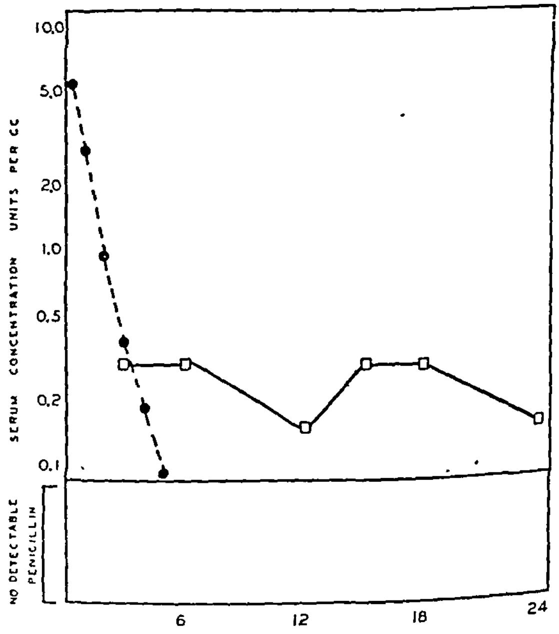

Fig. 2.—Comparison of serum concentrations of penicillin following single doses of aqueous sodium penicillin G and procaine penicillin in oil. The unbroken line represents sodium penicillin G (300,000 units in sesame oil), and the broken line presents sodium penicillin G (300,000 units in aqueous solution). The horizontal row of figures at the bottom shows the number of hours after administration.

[8] Tompsett, R.; Shultz, S., and McDermott, W.: Influence of Protein-Binding on the Interpretation of Penicillin Activity in Vivo, Proc. Soc. Exper. Biol. & Med. 65: 163, 1947.

From observations at the bedside of patients treated with these two dosage schedules, it has been impossible to distinguish any differences in the clinical results in the two groups, in spite of the obvious differences in the type of administration of penicillin. In early observations, impressions were gained that differences existed in the rate of defervescence and in the speed with which various symptoms abated. Further experience, however, has not borne out these impressions, and at present it seems unlikely that there are real differences of this sort between the responses to the two types of treatment.

The most graphic representation of the therapeutic effectiveness of penicillin in a patient with pneumonia has always been the patient's temperature chart. It is of interest, therefore, to compare the temperature curves of the patients receiving crystalline sodium penicillin G with discontinuous therapy with those who received procaine penicillin. For this comparison, calculation has been made of the mean temperature of each group of patients for each day of the first week of treatment. The same calculations were also made in 20 consecutive patients with pneumococcic pneumonia treated during the previous year with 20,000 units of aqueous penicillin intramuscularly every two or three hours. The three composite temperature curves obtained in this way are illustrated in figure 3. In each curve the first point represents the mean temperature of the entire group just prior to the start of therapy. Each additional point is the mean temperature for a twenty-four hour period and is derived from 60 to 120 values. The similarity of these composite curves is even closer than one might have anticipated. The uniformity of the temperature response is even more striking when one considers that it occurs in spite of many variable factors, such as age, nutritional state and various associated diseases, which might influence the response to treatment.

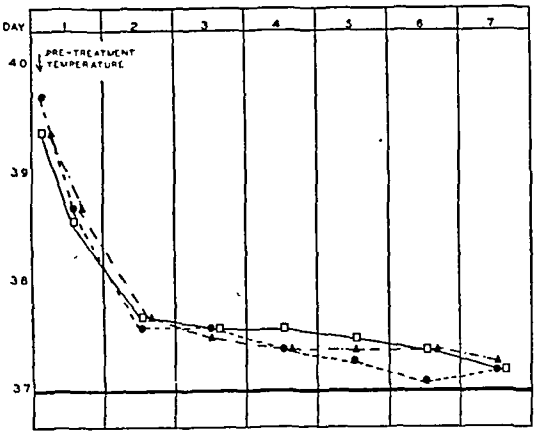

Fig. 3.—Mean temperature with three dosage schedules of penicillin therapy in pneumococcic pneumonia. The broken line represents discontinuous therapy (19 patients); the unbroken line represents procaine penicillin (21 patients), and the line of dots and dashes represents a schedule of 20,000 units every two to three hours (20 patients).

It has been apparent from the outset, however, that it will be necessary to treat large numbers of patients if one is to evaluate accurately the comparative value of discontinuous therapy. In these small numbers of cases, figures on the incidence of complications and death are of little or no value. It is important, however, that a review of these cases of uncomplicated pneumonia include data on all the patients treated, regardless of what the eventual diagnosis proved to be.

In addition to the patients with proved pneumococcic pneumonia, 20 patients on the one ward received a discontinuous treatment and 11 on the other ward received procaine penicillin. All were thought to have uncomplicated pneumococcic pneumonia on admission. In all but 4 cases, the response to treatment and subsequent course were as favorable as in the cases just discussed, and it is probable that the admitting diagnosis was generally correct. They are considered separately solely because of our failue to obtain the complete data required to establish with certainty the diagnosis of pneumococcic pneumonia. The pertinent observations in the remaining 4 cases may be considered briefly.

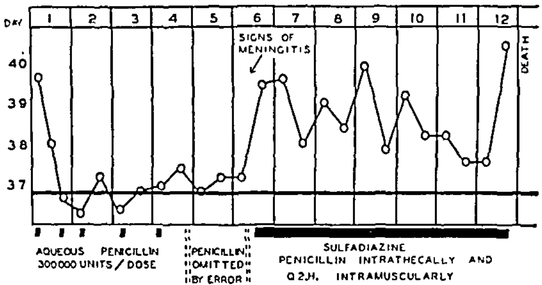

Fig. 4.—Graph of data for a 47 year old man under treatment for pneumonia who had type II pneumococcic meningitis.

Of the 4 patients in whom unfavorable results occurred, 2 received discontinuous treatment. The sequence of events, which was essentially the same in both, is of particular interest. In figure 4 is illustrated the course of a 47 year old man who was admitted with signs of pneumonia. Cultures of blood and sputum were positive for Pneumococcus type II. Although he was seriously ill at the time of admission, his response to treatment seemed prompt and his course at first favorable. On the fifth and sixth days, through an error he received no penicillin. Late on the sixth day he had a chill; signs of meningitis rapidly developed, and he died despite the intensive therapy indicated.

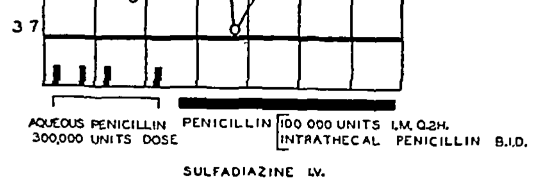

Fig. 5.—Graph of data for a 68 year old woman under treatment for pneumonia who had type III pneumococcic meningitis.

Figure 5 illustrates the course of a 68 year old woman who had pneumonia on admission. Blood culture and sputum culture were positive for Pneumococcus type III. Following an initial period of defervescence, a severe headache developed on the morning of the third day, and within a few hours she had evident signs of meningitis. Despite intensive treatment she died on the seventh day.

The outcome in these 2 patients must certainly be considered as failure of treatment. The question immediately arises as to whether meningitis would have ensued had penicillin been administered with one of the conventional dosage schedules. Unfortunately, it appears, from the available evidence, that none of the penicillin dosage schedules now used in pneumonia uniformly afford protection against the development of pneumococcic meningitis. Nevertheless, the events in these 2 patients suggest the possibility that suppurative complications which occur in patients receiving continuous therapy may occur with greater frequency if discontinuous therapy is used.

During the same period, death occurred in a patient treated with procaine penicillin. This patient was a 56 year old man who was critically ill when admitted on the sixth day of illness. He had signs of pneumonia, and type XXIX pneumococci were isolated from the sputum. He received procaine penicillin, and, although in the first twenty-four hours he appeared improved, he then rapidly became worse. The dosage schedule was then changed to 200,000 units of aqueous penicillin every three hours, but he died late on the second hospital day. Permission for autopsy was not obtained. This case must be considered as a failure of a continuous treatment schedule in pneumococcic pneumonia. Some doubt is cast on the diagnosis, however, by the fact that at the time of admission the blood culture was sterile and the total leukocyte count was only 6,800 per cubic millimeter.

The second patient who was treated with procaine penicillin and who may represent a treatment failure was a 17 year old boy admitted on the third day of illness. At the time of admission, no signs of fluid in the chest were noted on physical examination or in the roentgenogram of the chest. Only eighteen hours later, however, definite signs of a large pleural effusion were present and the diagnosis of empyema was confirmed by thoracentesis. Although empyema may have developed after the start of treatment, it seems likely that it was present at the time of admission, but not detected.

### USE OF DISCONTINUOUS THERAPY IN OTHER INFECTIONS

In the other part of the study, no attempt at simultaneous comparison of dosage schedules was made. Instead, the regimen of discontinuous therapy was instituted as a routine on the Infectious Disease Pavilion of the New York Hospital. Treatment was ordered by members of the resident staff who were free to choose other dosage schedules at the outset or were permitted to change to other schedules if they felt a patient's progress was unsatisfactory. Patients were also seen daily by members of the attending staff, in addition to those conducting the study.

During the fifteen months prior to reporting this dosage schedule proved to be satisfactory for use in the vast majority of patients admitted to this ward. In virtually all patients whose treatment was initiated in this way, the entire course of treatment was completed with no alteration in dosage. In a few instances, when, for one reason or another, it was decided that intensive penicillin therapy might offer added benefit, treatment was changed to doses of 50,000 units or more every two hours. In no patient thus far encountered has this change been of any obvious value. It should be emphasized, however, that discontinuous therapy has not been initiated in patients with such infections as staphylococcic bacteremia and subacute bacterial endocarditis, in whom it may be anticipated that intensive penicillin treatment will be required. These patients, however, make up a relatively small proportion of the total number to whom penicillin is given.

Thus far, this treatment regimen on this ward has been used in a total of 104 patients with a variety of infections. Of this total, 59 patients had the clinical evidences of bacterial pneumonia, and in 25 the diagnosis of pneumococcic pneumonia could be established with certainty. The ages of the patients with pneumococcic pneumonia ranged from 15 to 83 years, the average age being 48. Four had positive blood cultures. The average maximum leukocyte count for the group was 20,300 per cubic millimeter. Seven patients had heart disease, and 2 of these had frank signs of heart failure. In all of these 25 cases of pneumococcic pneumonia, the course under treatment with penicillin appeared in no way to differ from that observed with conventional dosage schedules, and no suppurative complications or deaths occurred. It should be noted that some of these patients received two daily doses of penicillin for more than one day. In only 6 of the 25, however, were two daily doses continued for more than two days. It is of interest, also, to note that in 4 patients only one daily dose of penicillin was given throughout the entire period of treatment.

In addition, 2 patients had pneumonia thought to be caused by group A hemolytic streptococci. In 1 of these it occurred in association with measles. In the other, streptococci were isolated from a small metastatic abscess of the skin. Both patients recovered promptly after treatment was initiated. The only death was that of a 69 year old woman with cardiac failure and chronic renal disease. On admission, signs of pneumonia were present and culture of the sputum yielded only Staphylococcus aureus. After the institution of treatment she rapidly became afebrile, and it was felt that the infection was being controlled. She remained afebrile and had no further leukocytosis, but the signs of cardiac failure and uremia progressively increased. She died on the seventh hospital day, five days after the time of defervescence.

In the remaining 31 patients treated for pneumonia on this ward, the etiologic diagnosis was not established. Patients who proved to have primary atypical pneumonia have been excluded as well as possible from consideration here, and it is felt that from the clinical observations and the response to treatment the great majority probably had pneumococcic pneumonia. In no case did any untoward event occur which was attributed to the possibility that insufficient penicillin was being given.

The remainder of the cases in which it was thought possible to judge the occurrence of a response to therapy included examples of the following infections: hemolytic streptococcic pharyngitis, fusospirochetal infections of the pharynx and buccal mucosa, scarlet fever, erysipelas, cervical adenitis, cellulitis secondary to lacerations or other trauma, pneumococcic tracheobronchitis and generalized staphylococcic pyodermia. In all of these cases, evaluation of the treatment is difficult because of the natural tendency toward spontaneous recovery. It can only be stated that in no instance was progression of disease observed or other events which would seem to denote failure or inadequacy of penicillin therapy.

### DEVELOPMENT OF ANTIBODIES

Studies by Weinstein and Tsao [9] and by Kilbourne and Loge [10] have shown that treatment of certain streptococcic infections with penicillin may prevent the usual development of antistreptolysin. The latter investigators observed also that the discontinuous administration of penicillin interfered to a considerably less extent with the development of antistreptolysin than did continuous treatment. The eventual significance of these differences in relation to the occurrence of late nonsuppurative complications is of great interest. Although of no obvious importance in relation to recovery from pneumonia, it seemed of interest to determine whether there were differences in antibody formation in patients with pneumonia who were treated with different dosage schedules of penicillin. The data thus far obtained on the development of specific agglutinins in patients receiving discontinuous and continuous therapy are insufficient to permit final conclusions on the comparative time of development of agglutinins and the height of the antibody rise in the two groups. Thus far, however, specific agglutinins have been observed in approximately the same proportion of cases in both groups, and no differences in the titer of antibodies are apparent.

### SUMMARY

A study has been made of therapeutic effectiveness of discontinuous penicillin therapy, consisting of one or two daily doses of penicillin in aqueous solution. Since March 1947, this dosage schedule has been used in the treatment of 125 patients with various acute infections, including 44 patients with pneumococcic pneumonia.

From observations thus far made, it appears that this treatment regimen provides entirely satisfactory therapy for the great majority of penicillin-susceptible infections. It should be emphasized, however, that such discontinuous therapy presumably would be inadequate in the treatment of serious staphylococcic infections, bacterial endocarditis and certain other rarely encountered infections which usually require large quantities of penicillin. Moreover, on theoretical grounds, it is possible that discontinuous penicillin therapy might not be the equal of intensive continuous therapy in the prevention of nonsuppurative complications of group A hemolytic streptococcic infections. Finally it should be emphasized that, from the observations in 2 patients with pneumococcic meningitis, the possibility is suggested that certain suppurative complications which occur in patients receiving continuous treatment may occur more frequently if discontinuous treatment is employed. Nevertheless, the clinical results observed in the treatment of pneumococcic pneumonia and other frequently encountered infections indicate that highly effective penicillin treatment may be provided by discontinuous therapy without the rigid restrictions imposed by conventional dosage schedules and dosage forms, which are based on the concept that continuous levels of drug in the body are required. More extensive clinical trial is necessary, however, to obtain a precise evaluation of the comparative value and the limitations of discontinuous therapy.

### ABSTRACT OF DISCUSSION

**Dr. W. W. G. Maclachlan**, Pittsburgh: The present method of continuous regular intramuscular injections has certain disadvantages, chiefly in that it requires someone to give the injections at regular two to four hour interevals. This method has been effective. Dr. Tompsett has presented a procedure of giving penicillin in a fairly large dose at long intervals of time. According to his clinical observations the results in treatment, as compared with the continuous method, are the same. His method simplifies and improves the intramuscular injection method of therapy. Other methods of therapy may also be improved. The probable chief reason why the sulfonamide drugs were so widely and effectively given by physicians was that oral therapy was the method of choice. My associates and I have been interested in treating pneumococcic pneumonia with penicillin by mouth. In the past year we have had cases of severe pneumococcic pneumonia in Pittsburgh, at least, in our clinic. Seventy-four patients were treated by the oral method, while 75 were given the regular three hour intramuscular injection of 25,000 units per injection for a total of 500,000 units, or a little more in some cases. The mortality rate in the group receiving the drug orally was 8 per cent, while that for the group receiving intramuscular therapy was 9 per cent. In 74 patients with bacteremia treated orally with penicillin there was an incidence of positive cultures of 29 or 39 per cent and a 10 per cent mortality rate. In the group treated intramuscularly, 75 patients, 19, or 25 per cent, had bacteremia, with a 15 per cent mortality rate. These figures would indicate that one can freely recommend, to the physician who is distant from hospital facilities, that orally administered penicillin is effective in pneumococcic pneumonia. I give a tablet containing 100,000 units every hour for six doses and then one every two hours for eighteen doses, or 24 tablets, 2,400,000 units in all. This dosage is about four times the amount which had been given by intramuscular injection, which is in keeping with the experimental studies. There is no reason to feel that this oral method cannot be altered. Perhaps it may be susceptible to the same type of change that Dr. Tompsett made in continuous intramuscular therapy. In any case, two methods of simplified penicillin therapy are available.

**Dr. Frederick H. King**, New York: Two facts have become increasingly clear. First, in some infections at least the continuous maintenance in the blood of a so-called therapeutic level during a twenty-four hour period is not essential to the achievement of clinical cure; secondly, the attainment of inordinately high blood levels does not necessarily result in hastening or even insuring a favorable therapeutic result. Moreover, if the hypothesis of Eagle that the production of excessively high levels may paradoxically lessen the effectiveness of the antibiotic should prove to be correct in vivo, then the production of high levels may not only be unnecessary but in fact be undesirable. To the former thesis, namely, that continuous blood level is unnecessary in certain infections, a concept already suggested by previous workers, Dr. Tompsett and his colleagues have brought powerful support. In a negative way, our experience supports the contention of Dr. Tompsett and his co-workers, who, like Marshall, believe that physicians have attached to blood penicillin levels an intrinsic significance which is not warranted. With the aid of carinamide my co-workers and I have been able to maintain for relatively long periods high levels of over 50 units per cubic centimeter and peak levels as high as 300 units per cubic centimeter. However, we have not been successful in demonstrating in clinical trials the superiority of such high levels over levels previously regarded as optimum, though it must be mentioned that we confined ourselves to diseases such as subacute bacterial endocarditis, which is more resistant to therapy than those diseases enumerated in this study. For instance, with such massive doses as 14,000,000 units per day for ten days and the persistently high levels achieved with carinamide, we were able to obtain a clinical cure in only 1, or possibly 2, out of 8 cases of subacute bacterial endocarditis—an experience which convinced us that such a regimen offered no advantage, at least in this disease, over prolonged treatment with smaller doses and lower levels.

[10] Kilbourne, E. D., and Loge, J. P.: The Comparative Effects of Continuous and Intermittent Penicillin Therapy on the Formation of Antistreptolysin in Hemolytic Streptococcal Pharyngitis, J. Clin. Invest. 27: 412, 1948.

Dr. Tompsett: I should like to take this opportunity to disclaim any originality for the principles involved in this therapy. In this study, we felt that we were only attempting *a more extensive demonstration of certain principles which* had already been established. I should like also to suggest that continuous and discontinuous treatment actually may be different in certain rather subtle ways, which may not be so immediately apparent. Kilbourne and Loge recently observed that in hemolytic streptococcic pharyngitis discontinuous treatment interferes with the development of antistreptolysin much less than does continuous treatment. This observation is of interest, particularly in that it may have some bearing on the development of late nonsuppurative complications of this disease.

# USE AND MISUSE OF ENDOCRINE THERAPY IN STERILITY

EDWARD T. TYLER, M.D.
Los Angeles

With the increasing availability of potent endocrine products, these substances have had an extensive range of clinical application. However, despite advances in knowledge of the physiologic relationships of endocrines, clinical therapy has been in many circumstances a "hit and miss" affair. Notably has this been true in the field of infertility, where various of the so-called sex hormones have been employed with extremely variable results. Such variability may be ascribed, in considerable measure, to the complexities of the sterility problem and perhaps to the disproportionate attention to the hormonal factors. In this connection, it cannot be overemphasized that normal fertility in a mating entails a number of important factors, only some of which are disturbed to any clinical extent by endocrine disorders.

The requisites for normal fertility in the female may be summarized as: (1) normally functioning ovaries, in which there is cyclic maturation of a graafian follicle with ovulation and subsequent corpus luteum formation, (2) a normal uterus, reactive to stimulus of the sex hormones, (3) a patent and receptive genital tract, which permits adequate migration of sperm and egg and subsequent travel of the fertilized egg to its site of nidation, (4) protection and nourishment of the developing embryo and (5) safe delivery.

The requisites for normal fertility in the male are: (1) production of adequate numbers of sperm, (2) secretion of a fluid medium favorable for conveyance of sperm, (3) a patent ductile tract, permitting transport of the sperm into the vaginal canal, and (4) adequate performance of coitus.

Despite the fact that considerable attention has been given to endocrine factors in sterility, hormonal disturbances are not the most important cause of involuntary childlessness. Winson,[1] for example, in analyzing a series of 257 cases, found tubal occlusion to be the most important female causative factor, occurring in 54 per cent of the cases. Guerrero[2] found tubal factors in 44 per cent of a large series of women, with hormonal causes occurring in 23 per cent. My observations indicate that endocrine causes constitute only about 20 to 25 per cent of involuntary sterility. This fact must be emphasized since the quantity of endocrine therapy utilized in this particular problem is frequently out of proportion to hormonal etiologic involvement. Accordingly, there can be no substitute for the initial accurate evaluation of the infertile couple or for a thorough investigation to uncover the underlying pathologic condition, whatever that may be. While space does not permit a complete description of what constitutes adequate evaluation, it may be summarized that a routine detailed investigation may require for the wife: a complete history and physical examination, complete blood cell count, determination of the sedimentation rate, urinalysis, determination of basal metabolic rate, blood cholesterol and/or iodine, vaginal smears for hormonal effect, endometrial biopsy, tubal insufflation and/or salpingography, postcoital examinations of cervical and vaginal secretions and studies of basal temperature curves, as well as, on occasions, hormonal assays. In the man, evaluation requires complete history and physical examination, determination of basal metabolic rate, blood cholesterol and/or iodine, repeated semen examinations and, in some instances, testicular biopsies, hormonal assays and studies of the ductal apparatus.

There is no real short cut to a thorough investigation, for most cases of infertility involve more than a single causative factor. After careful and extensive study, indications for endocrine therapy may become apparent, and when such therapy is limited to these cases the inconsistency of results should be substantially reduced.

## ENDOCRINE PHYSIOLOGY IN REPRODUCTION

The functions of all the endocrine glands are undoubtedly interrelated, and hence it would be an erroneous concept to isolate specific glands as those, alone, involved in the reproductive process. However, I shall limit discussion to those hormones the activities of which are most directly concerned with fertility.

According to current knowledge, the gonadotrophic secretions of the anterior pituitary are believed to be the primary controlling hormonal influence on the male and female gonads. In the female, the two gonadotrophic factors, follicle-stimulating hormone (F.S.H.) and luteinizing hormone (L.H.) are said to act in a cyclic manner during the menstrual cycle. During the first half of the cycle the activity of the follicle-stimulating hormone predominates and causes growth and development of the graafian follicles together with secretion of the follicular (estrogenic) hormone. In the second half of the cycle, the luteinizing hormone stimulates development of the corpus luteum and hormonal secretion from this latter structure (figure). The two ovarian hormones, namely estrogenic and corpus luteum, act on the auxiliary sexual apparatus, producing various effects. From the point of view of fertility, the most significant of these are the cyclic actions on the uterus. During the first half of the cycle, estrogenic hormone causes proliferation of the endometrium, and during the second half of the cycle—superimposed on the estrogenic influences—the corpus luteum induces secretory changes in the endometrium, preparing it for nidation. Should pregnancy occur, continued and increased elaboration of hormones from the corpus luteum takes place, and this structure con-

tinues to develop. During the fourth month of pregnancy, however, the placenta largely takes over the production of the three types of hormones; gonadotropes, estrogens and corpus luteum.

In the male, the gonadotrophic hormones are believed to be the same as in the female. Follicle-stimulating hormone stimulates sperm production, and luteinizing hormone stimulates secretion of the male sex hormone. This latter substance, in turn, acts on the secondary sex structures, including seminal vesicles, effecting their normal functions.

It should be noted that production of sperm and production of male sex hormone are related to the pituitary rather than to each other and that, according to current concepts, the male hormone does not act directly on the testes to influence sperm production.

### ENDOCRINE THERAPY IN THE FEMALE

*Failure of Ovulation.*—Probably one of the most frequently treated functional disorders in infertility is failure of ovulation. It has been amply demonstrated that regular cyclic vaginal bleeding in the absence of ovulation can and does occur.[3] However, the frequency of this condition is debatable. There is no completely reliable direct evidence of ovulation other than the actual visualization of a newly formed corpus luteum. The best indirect evidence of ovulation is, of course, the appearance of the premenstrual endometrial biopsy specimen. For practical purposes in the study of sterility, the endometrial biopsy specimen is taken within twelve hours after the onset of the menstrual period, since, if bleeding is awaited, there is little possibility of disturbing a pregnancy. The histologic observation of endometrium in the nonsecretory phase is strongly suggestive of the lack of corpus luteum function and hence lack of ovulation.

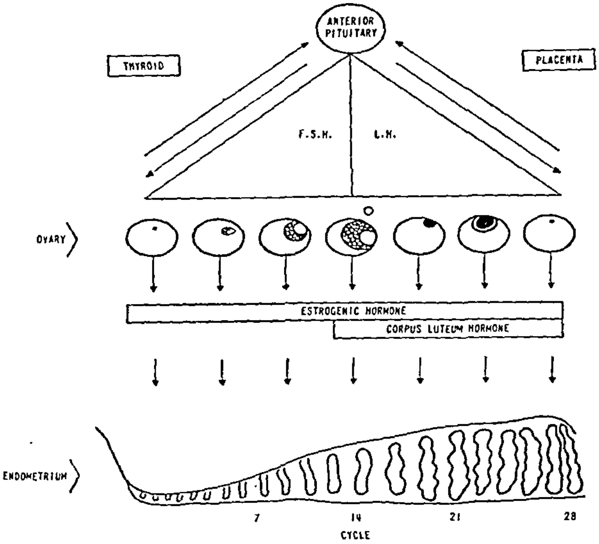
Hamblen,[4] Mazer and Israel[5] and others have pointed out that while the biopsy is in general a reliable test, in interpretation one must always take into account the fact that the endometrium may be refractive to corpus luteum and that, in some cases, ovulation may have occurred even when a proliferative phase endometrium is obtained.

Basal body temperature curves offer good guides to the occurrence of ovulation; in fact, when studied over a number of cycles, temperature curves may furnish more complete knowledge than an isolated biopsy. Tompkins[6] and others have emphasized the biphasic nature of the menstrual curve during the normal ovulatory cycle. The observation of monophasic curves in several cycles is suggestive of repeated anovulation.

Despite the fact that treatment of anovulation is relatively common, there are few statistical estimates of a high incidence of this particular condition. Sharman[7] in 335 endomentrial biopsies found that in only 23 were there definite signs of anovulatory cycles. Mazer & Israel[5] stated the belief that some anovulatory cycles are found in 16 per cent of sterile women, regardless of the primary cause, and in 30 per cent of sterile women in whom no other cause of sterility is found.

Even on the basis of these latter figures, certainly not more than 1 out of every 3 or 4 infertile women would require treatment for anovulation, a fact which must be considered before resorting to any stimulative therapy.

Endocrine therapy of anovulation has not been too successful. Preparations of various pituitary gonadotropins have been used rather extensively with rather conflicting results. The type of preparation which would be expected to prove successful is that containing large amounts of follicle-stimulating hormones. Two types of follicle-stimulating hormone preparations are commercially available, those derived from (1) pregnant mares' serum (P.M.S.) and (2) pituitary tissue. The former group has been more extensively employed clinically. Siegler and Fein,[8] Hall[9] and others have reported some encouraging results with pregnant mares' serum, whereas Geist, Gaines and Salmon[10] and Erving, Sears and Rock[11] stated that they did not believe that this material is effective in inducing ovulation.



Pituitary, ovary and endometrium relationship.

One important obstacle in the problem is the lack of establishment of accurate dosages, which will induce normal, and not excessive, follicle development. There has been evidence of excessive follicle stimulation with some of these substances and the concomitant possible development of cystic ovaries.

There is, also, the possibility of untoward allergic reactions, since these preparations are of a protein nature. Several serious reactions have been reported. Our usage of preparations of pregnant mares' serum has been relatively disappointing, and we believe that such therapy, if employed, should be considered definitely experimental, requiring very close supervision of the patient.

*Infantile Uterus.*—A hypoplastic uterus is frequently but one feature of a generalized state of hypogonadism. On occasion, however, the uterus may be poorly developed while other manifestations of gonadal function are fairly normal. In the presence of an infantile uterus, pregnancy may not readily occur, or, if it does, there may be predisposition to abortion. In some instances, development of the hyoplastic uterus can be induced by estrogenic therapy. Dosage should be rather heavy and preferably in cyclic form, to avoid interference with the menstrual flow. Therapy is started on the last day of each menstrual period and continued for three weeks, for three, four or more cycles. A daily dosage of 5 mg. of diethelstilbestrol is recommended, or the equivalent in other orally administered estrogens, such as dienestrol, hexestrol or conjugated estrogens.

*Poor Corpus Luteum Function.*—In some instances ovulation occurs, yet subsequent development and activity of the corpus luteum are below normal. The endometrium will then fail to develop full secretory changes and hence be inadequate for nidation and maintenance of the early embryo.[11a] This condition may be disclosed by the observations of repeated biopsies which show only poor secretory changes late in the cycle. Basal temperature curves with gradual rather than abrupt midcycle elevations are also suggestive of poor corpus luteum effect, although there is considerable disagreement on this point.

Therapy may be either (1) stimulative, with gonadotrophic hormone, or (2) substitutional, with corpus luteum hormone. Because of its more consistent action, substitution therapy with corpus luteum is probably the method of choice. Progesterone, 10 mg., is given intramuscularly, starting the eighteenth day of the cycle and continuing until bleeding occurs. If menstruation does not occur, the same dosage is continued until about the fourth month and then reduced to one every third day until fetal motion is felt. Potent corpus luteum hormone may be used orally, but this has the disadvantage of being considerably more costly in comparable dosage. If oral therapy is to be employed, a daily dosage of 40 mg. of pregneninolone is recommended. With the cost of this medication averaging about 25 cents for each 10 mg. tablet, it is obvious that continuous use may represent a financial burden. Orally administered preparations of corpus luteum derived from the gland itself have not been shown to have any clinical effectiveness; while many of these are inexpensive, they are also worthless.

*Habitual Abortion.*—The fairly large group of women in whom conception may occur with relative frequency only to terminate in spontaneous abortion may for practical purposes be considered infertile. Here again endocrine therapy appears to offer fascinating possibilities; yet it is generally believed that most causes of habitual abortion are not on an endocrine basis. A great percentage are attributable to defective germ plasm, local pelvic pathologic conditions, constitutional conditions, trauma and the like.[12] Of those attributable to hormonal disturbances, the exact etiologic mechanisms are obscure.

Because of the early experimental physiologic observations that corpus luteum hormone was responsible for maintaining the uterine musculature in a quiescent state during pregnancy, much therapy of habitual abortion has involved the use of corpus luteum hormone.[13] However, recent reports indicate that progesterone, alone, is not a particularly valuable agent in habitual abortion. Vaux and Rakoff,[14] for example, stated the opinion that, since both progesterone and estrogen play an important part in the maintenance of gestation, the use of either one of these alone is unphysiologic. They have advocated combined therapy with both progesterone and estrogens, starting as early as pregnancy is diagnosed and continuing until the period of viability. Both hormones may be given in one injection with a preparation which contains 10 mg. of progesterone and 1 mg. of estradial trimethyl acetate per cubic centimeter.[15] One cubic centimeter is given three times weekly.

Another point of view of endocrine therapy in habitual abortion has been advanced by Karnaky,[16] Smith and Smith and Hurwitz,[17] Greenhill [18] and others, who have used large doses of estrogens alone. Superficially, this would seem to contradict the known functioning, since estrogens are believed to stimulate uterine contractions. However, recent experiments provide some physiologic basis for such usage. Smith and Smith have demonstrated the important fact that in pregnancy diethylstilbestrol increases the production of corpus luteum hormone.

Kurzrok [19] has advocated the view that many cases of habitual abortion are associated with genital hypoplasia and that estrin administration promotes growth of the uterus, enabling it to keep pace with the developing fetus.

When used alone, diethylstilbestrol dosage is high. Greenhill [18] recommended 10 mg. daily, while Karnaky and others have advised at least 25 mg.

*Thyroid Hypofunction.*—It has been said, with perhaps some justification, that the use of thyroid substance has been the most important hormonal therapy of infertility. However, the exact value of thyroid is open to considerable conjecture. Despite the fact that numerous reports have appeared, advocating its routine use in sterility, regardless of the basal metabolic rate and other factors, the statistical evidence in favor of such usage is not too impressive. Reports giving cures in perhaps 30 per cent of patients given thyroid are subject to the criticism that the incidence of spontaneous cures in infertility may be nearly as high. Rabau, discussing therapy in sterility,[20] emphasized this fact in his series of 792 cases. Since thyroid is a routine measure so frequently, it may be given the credit for that which is in fact a spontaneous cure. Naturally, the same criticism holds for all types of therapy, but in the case of thyroid its commonplace usage makes it more suspect.

From the scientific point of view, thyroid extract should be given only in the presence of hypothyroidism. Such hypofunction can be diagnosed on the basis of clinical symptoms, basal metabolic rate, blood cholesterol and blood iodine. A slight decrease in the basal metabolic rate per se does not mean hypothyroidism. (Conversely, patients who appear somewhat

hypothyroid clinically may not possess a significantly low basal metabolic rate.) The prescribing of thyroid solely on the basis of mild lowering of the basal metabolic rate, in the presence of all other evidences of normal thyroid function, is not justifiable.

It has been shown adequately that, while the administration of thyroid in normal persons may temporarily provide an increase in the basal metabolic rate, this increase will not persist, and with the same dosage the basal rate will revert to the original level or even lower.[21] Furthermore, when medication is discontinued, there is a period of reduced basal metabolic rate for several weeks before the return to its original level. This is attributable to the suppression of the patient's own thyroid function by the exogenous thyroid.

One feature of thyroid therapy which may to some extent explain its popularity is the fact that thyroid is a highly potent oral substance, and hence when given it "does something." However, by the same token, it must be emphasized that controlled studies of infertile patients who have been successfully treated with thyroid are few and far between. This should not be taken as disproportionately harsh criticism of thyroid therapy, but rather as an effort to emphasize that there is a definite question as to its routine value. The literature is correctly filled with much criticism of other endocrine preparations; yet thyroid seems to occupy a perfectly respectable place, despite the fact that injudicious use of this substance may be equally harmful.

On the other hand, if there is an element of hypothyroidism, it is logical to assume that the metabolic stimulus provided by thyroid administration may be just the impetus required to increase gonadal function to the fertile level.

*Miscellaneous.*—Endocrine preparations have been utilized in a variety of other conditions associated with infertility in the female, and certain of these seem to show promise. For example, estrogenic therapy was found to improve the viscosity and quality of cervical mucus,[22] and a combination of estrogens and sulfadiazine has been recommended as a substitute for cauterization in clearing up the chronic endocervicitis, which at times appears as an important barrier to conception.[23]

Estrogenic therapy has also been suggested in instances when tubal motility is not normal; it is felt that such therapy increases tubal peristalsis. Experimental work in connection with tubal spasm is also being conducted utilizing testosterone.

## ENDOCRINE THERAPY IN THE MALE

The study of male infertility is still in its very early stages. The causes of many disturbances are obscure, and treatment is frequently unsatisfactory.

Two major conditions in which hormones may be involved in male disturbances are: (1) impotence and (2) defective spermatogenesis.

*Impotence.*—The ability to perform coitus, while a manifestation of endocrine normality, is also dependent on various neurogenic, psychogenic and mechanical factors. From the clinical point of view, the cause in the majority of cases of impotence is not primarily endocrine in origin and requires other therapy. In those cases in which the condition has an endocrine basis there will generally also be inadequate spermatogenic function, with other signs of hypogonadism. The majority of the patients have eunuchism or various stages of eunuchoidism. It is not common to see patients showing a combination of normal sperm production with impotence on the basis of hormone failure. In those patients in whom this does occur, rational treatment may be with the male hormone. The clinically effective dose of this substance is 25 mg. of testosterone propionate three times weekly. The equivalent oral dose is approximately 30 mg. of methyl testosterone, or 20 mg. given sublingually in the form of linguets.

*Seminal Deficiency.*—The majority of infertile husbands show normal ability to perform coitus, but have seminal deficiencies. Unfortunately, results of hormonal therapy in these cases are not encouraging. Stimulation of sperm production is directly dependent on secretion of the pituitary gonadotrophic hormone, follicle-stimulating hormone, the same hormone which produces follicular development in the female. Unfortunately again, the clinical experience with follicle-stimulating hormone preparations in the male are even more discouraging than in the female. If testicular biopsy is employed prior to therapy, many cases will be shown to merit no therapy because of irremediable damage to the seminiferous tubules.

The author has on occasion achieved some improvement in count by administration of gonadotrophic hormone in cycles and advising the patient to abstain from intercourse except at the period of the cycle during which ovulation may be expected to occur.[24] In that way, the best specimen may be obtained at the time when conception is most possible. There is, however, no evidence that spermatogenesis per se is improved in these patients to any substantial degree.

A new steroid, pregnenolone, has shown spermatogenic activity in experimental animals, but clinical investigation of this substance has failed to demonstrate significant therapeutic effectiveness.[25]

Testosterone propionate has been used frequently in the treatment of spermatogenic deficiencies, but such usage is not physiologic, since the male hormone does not directly stimulate activity of the seminiferous tubules. As a matter of fact, suppression of sperm production with the administration of large doses of testosterone has been reported. While this can undoubtedly occur, it is my impression that in the moderate dosage generally used, such suppression does not occur.

In instances in which the sperm count is fairly normal, but when motility may be somewhat impaired, small doses of testosterone may prove helpful by virtue of its effect on secretion of the prostate and other secondary sex glands. When used for this purpose, however, dosage should not exceed 10 mg. of testosterone propionate twice weekly or the equivalent in the form of methyl testosterone linguets.

The use of chorionic gonadotrophin in treating spermatogenic deficiency is not on a physiologic basis, since luteinizing hormone apparently has no effect on spermatogenesis.

The use of thyroid, in my opinion, should be limited to those patients who are hypothyroid, as discussed elsewhere in this paper.

Some investigators have stated the belief that in the male many gonadal deficiencies are fundamentally nutritional in origin and that treatment with substances other than hormones, such as vitamin B complex, desiccated liver and vitamin A, provides more therapeutic possibilities. Unfortunately, the correlation of histologic observations and therapeutic responses is still obscure, and, for the present, therapy in the male is largely a matter of general constitutional measures, hygienic habits, adequate diet and the like, with the use of hormones playing a relatively minor role in the present state of knowledge.

### SUMMARY AND CONCLUSIONS

The physiologic relationships of the endocrine glands in reproduction are briefly outlined. The use of various endocrine preparations in some of the commonly treated aspects of infertility is discussed. The effectiveness of endocrine therapy in sterility is limited by the important facts that (*a*) the majority of cases of infertility are not endocrine in origin, (*b*) many of the preparations available are clinically ineffective and (*c*) exact diagnosis of some endocrine disturbances is difficult. There is no substitute for careful etiologic study of the patient, with therapy directed toward the specific factors observed.

*921* Westwood Boulevard.

## ABSTRACT OF DISCUSSION

Dr. Willard O. Thompson, Chicago: The problem of infertility involves many factors, some anatomic and some hormonal. One of our duties as physicians is to attempt to improve the quality of the race. It would be interesting to know what type of offspring results from our efforts to make it possible for persons who are relatively infertile to conceive. Is the product as good as it is in persons who have no infertility problem? It is extremely important that studies be carried out to determine just what the end result is. The problem reverts to the fundamental functioning of the gonads and pituitary, all the factors involved in the regulation of menstruation and in the elaboration of good spermatozoa. One of the most important contributions that the studies on infertility have made is some increase in the knowledge of the function of the gonads and the glands of internal secretion that are related to them, notably the pituitary. It is very desirable to continue these studies. Although examination of the spermatozoa is relatively simple, most spermatozoa counts and most observations on spermatozoa are improperly performed and of relatively little value. One constantly sees patients who are said to have few spermatozoa, in whom, on examination, one finds normal spermatozoa counts and spermatozoa which are normal in every respect. Spermatozoa counts are not difficult, but the technic has to be carried out accurately. The female presents a more complex problem. Several types of abnormality may be found in the female, from the physical point of view, the congenital point of view and from the point of view of hormone disturbances. These can be accurately determined only by the most careful examination, which frequently involves careful hormone assays. Certain endocrine products are of definite value in the treatment of infertility. It is occasionally possible, with the pituitary gonadotropins available at the present time, to induce ovulation in women with an ovulatory menstrual cycle. I should like to emphasize what Dr. Tyler pointed out, namely, that desiccated thyroid has been very much abused in the treatment of sterile couples. Desiccated thyroid is primarily of value when hypothyroidism is present. There is a close relationship between the thyroid and gonads, but it is effective only when there is a definite thyroid deficiency, and I should like to decry the wholesale use of desiccated thyroid in the treatment of sterile persons. The American Society for the Study of Sterility considers the problem of infertility so important that it plans to establish a separate journal.

Dr. Edward T. Tyler, Los Angeles: I wish to thank Dr. Thompson for his comments. I have been asked to say a few words about the enzyme hyaluronidase. I have used this substance clinically by packing it around the cervical os and also by adding it to the semen in artificial insemination. Results thus far do not appear to substantiate early clinical reports as to its therapeutic efficacy in certain types of infertility.

# MODERN HISTORY OF PERIPHERAL NERVE SURGERY

## World War II and the Postwar Study of Peripheral Nerve Regeneration

BARNES WOODHALL, M.D.
Durham, N. C.

It is perhaps a truism to state that the student of modern peripheral nerve surgery must be a student of military neurosurgery. Advances in this field, however, have always been directly related to two factors: (1) the decided increase in peripheral nerve injuries that always occurs as a result of war and (2) laboratory studies that have been embarked on because of the stimulus of problems that arise from this unusual mass of clinical material. For the purposes of this survey, the modern history of peripheral nerve surgery will be considered as starting in the latter part of 1942 and as reaching a clear end point with certain peripheral nerve regeneration studies now being conducted under the aegis of the National Research Council. This time limitation is admittedly an artificial one, and indeed the survey itself cannot be a complete one, but it covers a period in which some fifteen thousand peripheral nerve operations were performed and a later period in which at least an organized beginning was made in the objective study of the results of these procedures.

The general statement may be made that the recent progress of peripheral nerve surgery has rested more on a factual appreciation of the principles of nerve repair than on new methods of the technic of repair. There were, however, significant contributions to the age-long technical problem of securing an adequate end to end anastomosis, of overcoming large nerve defects by the implanting of a nerve graft and of controlling causalgic pain.

### SUTURE MATERIAL

The search for an ideal suture material was initiated early in the war with the introduction of tantalum wire rolled into a 0.003 inch (0.008 cm.) diameter and swedged to curved needles of equal size. This metallic suture proved to be relatively inert in tissue but demanded considerable manual dexterity in its application. The use of very fine silk was preferable to tantalum in the repair of nerves of fine caliber, such as the digital. The potential value of the metallic suture

---

Read in the Session on History of Medicine before the Section on Miscellaneous Topics at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

was immeasurably increased by the fact that the suture line could be visualized postoperatively by roentgenography of the site of anastomosis. This allowed the early fate of the integrity of the suture line to be followed at regular intervals and permitted the prompt recognition of suture line disruption. In a laudable effort to decrease the amount of tissue distortion at the suture line, and perhaps to decrease fibroblastic invasion at the point of anastomosis, several nonsuture methods of nerve repair were developed, notably the so-called plasma-glue suture. Its value was not fully delineated during the war experience, but it is reasonable to say that it is an auxiliary method of nerve repair to be used primarily in situations where suture line tension is minimal. One such situation is present when the adequate insertion of a nerve graft is contemplated.

### NERVE GRAFTING

Perhaps no problem in this field has titillated the ambitions of neurosurgeons more than that of nerve grafting, and undoubtedly more energy and talent were expended on this matter than it deserved during these difficult years. When the human experiments in this field were assayed, it was obvious that man could not be considered as simple a creature histologically as could the rabbit, the cat or even the monkey. In the face of repeated successes in the experimental animal, whole fresh homografts and autografts of large nerves showed lack of clinical regeneration and histologic evidence of extensive fascicular necrosis and fibrous tissue replacement. The frozen-dried and rehydrated homograft of large nerves was promising and merits further trial as a longitudinally oriented bridge for the ingress of regenerating axons into the distal stump. There was sufficient laboratory and clinical evidence to show that the critical period of self sufficiency of the implant was quite short and that the reestablishment of the blood supply of the graft was of paramount importance. Since there existed much evidence of the success of single autografts in the grafting of small nerves, such as the facial and digital, the use of multistranded or cable autografts in the repair of injured nerves was a logical sequel of these observations. Since the strands of cutaneous sensory nerves used to form the cable graft were small, the use of the plasma glue technic of suture was advocated. A recent answer to this problem has been furnished in the affirmative by our English colleagues, but obviously much still remains to be done.

### CAUSALGIA

No greater personal tragedy exists for the person with a major peripheral nerve injury than to have the pain of causalgia superimposed on his existing extremity dysfunction. The prewar years had demonstrated that such pain could be abolished by an appropriate denervation of the sympathetic nerve supply to the point of injury. The military experience in this field was fully exploited. Causalgia was found to appear in approximately 3 per cent of major nerve injuries and usually in instances of incomplete nerve division. In addition to the possible roles of vasospasm and local ischemia, direct cross stimulation of the sensory fibers by efferent sympathetic impulses at the point of nerve tissue injury was postulated as a theory that deserved serious consideration. Whatever the causation of this bitter pain may be, the relief by chemical or surgical interruption of the sympathetic nervous system occurred in such a high percentage of cases that failure could be explained only on the basis of inadequate denervation or the presence of neurosis or hysteria.

### PROPER TIME FOR SUTURE

The difficulty of appraising the many variables affecting the recovery process in peripheral nerve injuries is at no point better illustrated than in the complex evaluation of the proper time at which to perform a definitive nerve suture. The evidence against primary or immediate or emergency nerve sutures in war injuries was almost incontrovertible, and the American point of view has been supported by British neurosurgical opinion. The contraindications to immediate suture proved to be the presence of infection, the technical difficulties of suture and nerve segment mobilization and, above all, the inability of the surgeon to evaluate exactly the extent of pathologic change in the respective nerve ends. To obviate these difficulties, the so-called early nerve suture was advocated with the sequence of events somewhat as follows: (1) debridement of the wound, with or without approximation of the visualized nerve segment by a fixation suture, and the start of antibiotic therapy, (2) delayed closure of the wound after infection has been delimited, (3) definitive nerve suture at a time when wound healing was complete, three to six weeks after the initial trauma, (4) judicious limb immobilization during transportation and after nerve suture, preferably by removable splints, and (5) preoperative and postoperative physical therapy. This time of definitive nerve suture, as compared with immediate nerve suture, was still early enough to obviate regressive changes in the distal nerve segment and in the denervated extremity as a whole. Normal wound healing occurred in 98 per cent of cases, and a study of the early course of regeneration disclosed suture line failure in but 5 per cent of the cases, as contrasted to 22.4 per cent of failure in the immediate nerve suture group. Similar results were reported from the Mediterranean Theater of Operations.

The transfer of this principle of nerve repair to civilian injuries caused by entirely different wounding mechanisms is a controversial issue at this moment, an issue perhaps confused by a too strict interpretation of the war injury sequence of procedures. In civilian injuries, debridement and primary skin closure can be carried out. The nerve injury may be treated but once at a time when a difficult tedious dissection can be initiated in a clean operative field, as an elective operation, in a thoroughly prepared patient. It is indisputably true that the trained neurosurgeon can carry out primary nerve suture with excellent results, granted that the patient is in a receptive mood and physical status commensurate with the task at hand. Unfortunately, the majority of peripheral nerve injuries occur and are treated in the absence of such specialists. The war experience has in part exploded the fallacy that a nerve injury is an emergency problem. It may soon even attain the respectable stature of an elective procedure, carried out at 8 o'clock in the morning by a rested and informed surgeon on a patient prepared for any eventuality.

### PERIPHERAL NERVE REGISTRY

The Peripheral Nerve Registry of World War II was established by the Surgeon General on Nov. 22, 1944, with the twin purposes of studying neural regeneration during army hospitalization and at certain time periods during the postwar era. By the end of hostilities, about 7,000 nerve sutures and nerve grafts had been registered and a statistical study of the basic data of the Registry had been compiled. This roster of patients and the desirability of follow-up in neural regeneration in the postwar period was presented to the Conference on Post-War Research held by the Division of Medical Sciences of the National Research Council on April 18, 1946. From this conference report stemmed two meetings of interested neurosurgeons, neurologists and neurophysiologists, which resulted in formal application being presented to the Committee on Veterans Medical Problems of the National Research Council for clinical research in this field, eventually entitled Project 13, "Follow-up Studies of Peripheral Nerve Injuries in Veterans." Study centers have been established in Boston, New York, Philadelphia, Chicago, San Francisco and Durham, N. C., with the simple and primary purpose of studying the varying aspects of neural regeneration in the war injured by the best of research methods. These study centers are functioning at the present time. This is one of the most ambitious and far reaching programs that have ever been devised for the study of peripheral nerve regeneration. Its objectivity is attested to by the fact that precision methods of study are being supervised by neurologists and neurophysiologists, none of whom have ever been responsible for actual surgical treatment or have ever used specific methods of treatment. On the other hand, in each center an experienced military neurosurgeon, some of whom are administrative heads of the center, will examine each case and add to the studies their knowledge of the conditions under which the wounds were suffered and the principles under which the patient received definite therapy. The final results of these endeavors will greatly influence military neurosurgery, in terms of both treatment and the disposition of wounded soldiers. One may also confidently expect that such studies will define in some detail the application of the wartime experience to the similar problems of peripheral nerve surgery encountered in civilian life.

### CONCLUSION

Many years ago, Leonardo Da Vinci wrote these words about the peripheral nervous system, "The function of the nerve is to give a stimulus. They are the knights of the soul and have their origin from its seat, and command the muscles that move the members at the good pleasure of the soul."

Some of my colleagues who worked long and hard with these difficult injuries would feel that this were extravagant praise indeed. They would prefer never to have the subject mentioned again. Be that as it may, the study of this complex system is not complete; with the aid of modern research methods, the art of peripheral nerve surgery will continue to advance.

## ABSTRACT OF DISCUSSION

Dr. William J. Mixter, Boston: Dr. Woodhall failed to state that he himself is largely responsible for the advancement of our knowledge of peripheral nerve surgery. The other point I wish to make is that careful follow-up of patients with this group of nerve injuries will require the cooperation of all members of the medical profession who see these patients. It is essential that they be examined repeatedly. Therefore, the physician should urge that they report back for such examination.

# ANGIOCARDIOGRAPHIC STUDY OF THE PULMONARY ARTERY

CHARLES T. DOTTER, M.D.
and
ISRAEL STEINBERG, M.D.
New York

Congenital and acquired heart disease, as well as pulmonary disease, produce significant changes in the size and configuration of the pulmonary artery and its branches. Because of the intimate relation of the artery to the heart and the mediastinal structures, recognition of these changes in roentgenologic study of the pulmonary artery has hitherto been difficult. Groedel's careful description of a probable aneurysm of the pulmonary artery [1] demonstrates convincingly the difficulties presented to the roentgenologist in the anatomic diagnosis of pathologic conditions of the pulmonary artery. With the presentation, in 1938, by Robb and Steinberg,[2] of a practical method of visualization of the cardiovascular system with contrast medium, the entire bed of the pulmonary artery became readily accessible to roentgenologic examination. Angiocardiography has indicated a wide variety of pathologic states which are manifested, in part, in abnormalities of the pulmonary artery. It is the purpose of this paper to present an angiocardiographic study of the normal and the pathologic pulmonary artery.

### THE NORMAL PULMONARY ARTERY

The normal pulmonary artery is a short, broad vessel which arises from the conus arteriosus at the pulmonary semilunar valves to the left of the ascending aorta and then ascends, to the left and posteriorly, to a point below the aortic arch, where, just to the left of the spine, it gives off left and right main branches. The right branch passes posterior to the ascending aorta and the superior vena cava and anterior to the tracheal bifurcation, esophagus, thoracic duct and spine. to the hilus of the right lung, where it divides into superior and inferior branches. The left branch runs a short course to the hilus of the left lung; it is related posteriorly to the left main bronchus and the descending aorta and superiorly to the descending aortic arch, to which it is connected by the ligamentum arteriosum. Inferiorly, the right and left branches of the pulmonary artery are related to the pulmonary veins.

Though it is limited, conventional roentgenoscopy offers valuable information concerning the pulmonary artery. In frontal projection, the prominence immediately beneath the aortic knob is the shadow of the pulmonary trunk and its left main branch. This segment of the left cardiac border is abnormally prominent in dilatation of the pulmonary artery. In the lateral and both oblique projections, the upper anterior cardiac border is formed by the conus arteriosus and the pulmonary artery. The right auricular appendage plays

Investigation **17**: 507 (July) 1938; Visualization of, the Chambers of the Heart, the Pulmonary Circulation and the Great Blood Vessels in Man, Am. J. Roentgenol. **41**: 1-17 (Jan.) *1939.*

a role in the formation of the upper anterior border in the left anterior oblique projection. In the lateral and left oblique projections, the right branch of the pulmonary artery is often recognizable as a rounded area of density within the hilar shadows. Similarly, the end on shadow of the left main branch may occasionally be recognized in the right anterior oblique projection. Dilatations of the pulmonary portion of the outflow tract may be recognized, in the lateral and oblique projections, in increased prominence of the upper anterior cardiac border and in a diminished retrosternal space. An enlarged pulmonary artery may indent the barium-filled esophagus; this may be viewed on lateral projection.[3]

Angiocardiography has established the validity of the preceding observations and disproved certain erroneous assumptions regarding the part of the pulmonary portion of the outflow tract in the composition of the normal cardiac contour. In angiocardiographic literature, the fact has been repeatedly emphasized that the pulmonary conus plays no role in the formation of the left cardiac border in frontal projection.[4] Visualization of the pulmonary artery and its branches, using contrast medium, affords precise, anatomic observations. In the frontal projection, the pulmonary artery may be seen as an almost vertical shadow, terminating superiorly in its bifurcation. The right branch is clearly demonstrated in its horizontal course to the hilus of the right lung. The left branch of the pulmonary artery "sits upon" the pulmonary trunk, curving downward as it enters the root of the left lung. The superior margin of the left branch of the pulmonary artery is regularly 1 to 2 cm. higher than that of the right branch. The conus arteriosus is not sharply outlined in the frontal projection, although its outer termination is often indicated by the sinus above the left pulmonary semilunar valve.

In the lateral and both oblique projections, the distinction between the pulmonary artery and the conus arteriosus can usually be made with certainty. The sinuses of the pulmonary semilunar valves are seen as localized dilatations of the pulmonary part of the outflow tract, while the anterior cusp of the pulmonary valve can often be identified. Distal to this point, the pulmonary trunk proceeds posteriorly, making up a portion of the anterosuperior cardiac border. The pulmonary trunk and the conus arteriosus are best seen in the lateral projection.

Angiocardiography affords accurate measurement of the caliber of the pulmonary trunk and the right main branch. Measured in 50 normal persons, the right main branch of the pulmonary artery, as it crossed the spine in frontal projection, varied from 17 to 30 mm. in caliber, averaging 23.4 mm. The pulmonary trunk ranged from 20 to 30 mm., averaging 26.4 mm., while the pulmonary conus ranged from 16 to 24 mm. and averaged 19.1 mm. These measurements were made in oblique and lateral projections; complete details were presented in a previous article.[4c] A slight, progressive increase with advancing age was noted in the caliber of the pulmonary artery.

### THE PULMONARY ARTERY IN PATHOLOGIC CONDITIONS

*Congenital Heart Disease.*—Many of the commonly encountered, congenital cardiovascular abnormalities are manifested, in part, by morphologic or dynamic changes in the pulmonary artery. These changes, long recognized and well described in the literature of pathology and roentgenology, are best demonstrated in the living subject by means of angiocardiography. An abnormal pulmonary artery is present in every case of congenital "cyanotic heart disease." The most frequently observed change is that of dilatation of the pulmonary artery.

Primary or idiopathic dilatation of the pulmonary artery is less frequently encountered than secondary dilatation. Congenital lesions causing secondary or dynamic dilatation of the pulmonary artery include patent ductus arteriosus, septal defects (alone or in combination with other defects, as in Eisenmenger's syndrome) and pulmonic stenosis, wherein the artery is often widely dilated beyond the point of narrowing. The pulmonary artery may be small or absent in pulmonic stenosis (alone or in combination with other defects, as in the tetralogy of Fallot), in tricuspid atresia and in atresia of the pulmonary artery. Angiocardiography may be expected to reveal the pathologic anatomy of such congenital lesions as common truncus arteriosus, transposition of the great blood vessels, anomalous pulmonary arteries and veins and dextrocardia. Only those lesions commonly compatible with life beyond the first few years are included in our series.

*Congenital Aneurysm of the Pulmonary Artery.*—Idiopathic dilatation, or aneurysm, of the pulmonary artery is less rare a condition than has been previously supposed. Its recognition with angiocardiography is simple, and additional cases will probably appear in the literature with increasing frequency. In making the diagnosis, all other possible causes of dilatation of the pulmonary artery must be excluded, with clinical and roentgenologic means. We studied 2 cases of pronounced dilatation of the pulmonary artery in which no etiology other than congenital could have been implicated (fig. 1).

*Septal Defect.*—The relation between defects of the interatrial or interventricular septum and dilatation of the pulmonary artery is well known. Though either may cause dilatation, interatrial defects are more prone to cause pronounced dilatation of the pulmonary artery.[5] Probably the greatest secondary dilatation of the pulmonary artery occurs with an interatrial defect combined with mitral stenosis (Lutembacher's syndrome).[6]

*Patent Ductus Arteriosus.*—Dilatation of the pulmonary artery is the most common observation in the roentgenologic diagnosis of patent ductus arteriosus; it occurred in 41 of 50 proved cases reported by Donovan, Neuhauser and Sosman.[7] Steinberg, Grishman and Sussman drew attention to an elevation of the main and left pulmonary arteries in this condition.[4d] Our data are similar to these observations. In addition, we observed opacification of the ductus itself, with reopacification of the pulmonary artery. Figure 2 illustrates the reopacification of a dilated, elevated pulmonary artery in a case of clinically established patent ductus arteriosus. *Angiocardiography in this case ruled out the presence of septal patency and, in addition, revealed a localized dilatation of the descending aorta at the point of origin of the ductus, a sign first described by Steinberg, Grishman and Sussman.*[4d]

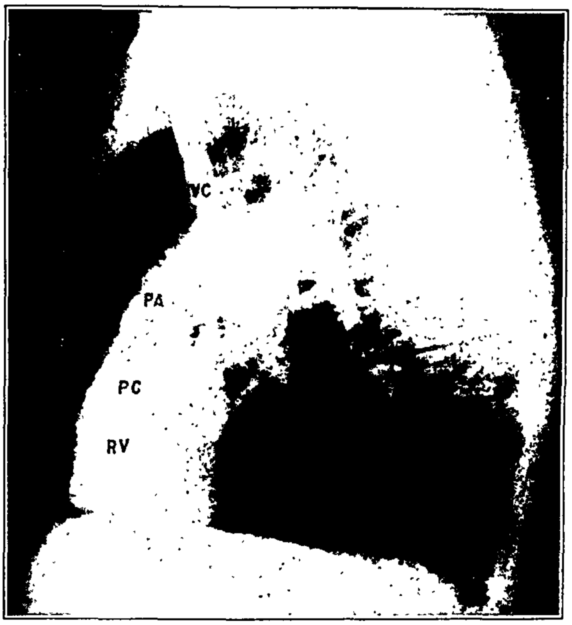

Fig. 1.—Congenital aneurysm of the pulmonary in a patient of 35 years; left lateral projection. SVC, superior vena cava. RV, right ventricle. PC, conus (conus arteriosus). PA, pulmonary artery. Note aneurysmal dilatation of the pulmonary trunk and its branches.

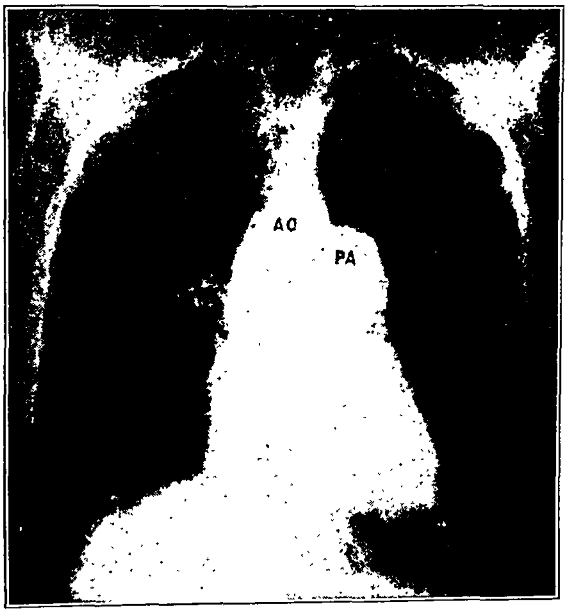

Fig. 2.—Patent ductus arteriosus in a patient of 29 years; frontal projection, ten seconds after injection. The aorta (AO) is opacified, and the reopacified, dilated pulmonary artery (PA) is outlined.

*Eisenmenger's Syndrome.*—The combination of interventricular septal defect, dextroposition of the aorta and a dilated or normal pulmonary artery, known as the Eisenmenger complex, is not amenable to surgical treatment. This is in contradistinction to the tetralogy of Fallot, where pulmonic stenosis is present and where great relief may be obtained with the surgical creation of a "shunt" from a peripheral artery to the hypotensive bed of the pulmonary artery. The angiocardiographic demonstration of a dilated pulmonary artery and pulmonary conus is a contraindication to an aortic-pulmonary anastomosis.

*Pulmonic Stenosis.*—Pulmonic stenosis is clearly revealed angiocardiographically; the exact location of the point of narrowing may be demonstrated. Stenosis usually occurs in combination with other anomalies but is often seen as an isolated lesion. In 2 patients, both of whom were noncyanotic, pulmonic stenosis was demonstrated angiocardiographically as an isolated lesion. In one case (fig. 3) the stenosis was infundibular, while in the other case (fig. 4) the site of narrowing was above the valve. Demonstrated in both cases was a dilatation of the pulmonary artery distal to the point of stenosis, often observed in coarctation of the aorta.[8]

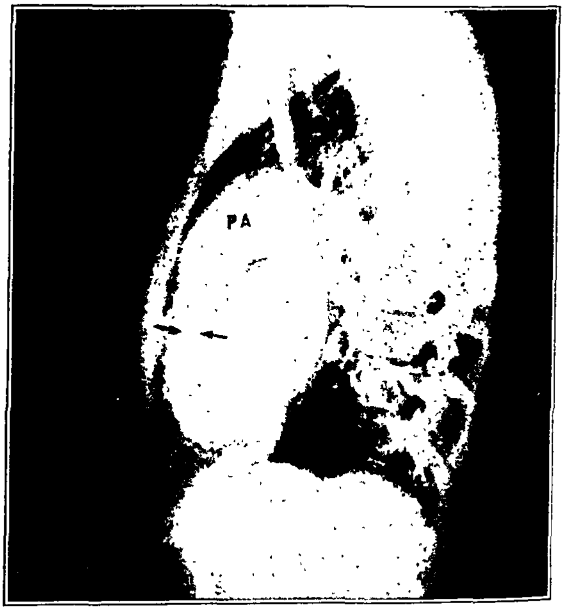

Fig. 3.—Infundibular pulmonic stenosis in a patient of 30 years; left lateral projection. Arrows embrace the point of stenosis below the pulmonary semilunar valves. *Note distal dilatation of the pulmonary artery (PA) and its branches.*

*Tetralogy of Fallot.*—Angiocardiographic visualization of the site of pulmonic stenosis in the tetralogy of Fallot should invariably be accomplished before operative intervention. As well as in ruling out the presence of the clinically similar Eisenmenger's syndrome and in confirming the diagnosis of septal defect and dextroposed aorta, angiocardiography is of great value in demonstrating to the surgeon the exact anatomic structure of the defect he plans to correct. In this manner, unnecessary delay during the actual, time-consuming operation may be avoided. In no other congenital cardiac abnormality is angiocardiography of such great value to the patient as in the tetralogy of Fallot.

8. Grishman, A.; Steinberg, M. F., and Sussman, M. L.: Contrast Roentgen Visualization of Coarctation of Aorta, Am. Heart J. **21:** 365-370 (March) 1941.

Figure 5 demonstrates the appearance in a case of tetralogy of Fallot.

*Rheumatic Heart Disease.*—Mitral stenosis due to rheumatic fever causes enlargement of specific chambers of the heart and, thereby, imparts characteristic changes to the silhouette. Among these are enlargement of the left atrium and enlargement of the right ventricle and its outflow tract, including the pulmonary artery and its branches. As has been previously reported, the pulmonary artery and its left main branch make up the prominence in the left upper cardiac border (viewed in the frontal projection), frequently observed in mitral stenosis.[9] In our series, dilatation of the pulmonary artery was not so important as elongation of the outflow tract of the right ventricle in producing this prominence. Rotation of the heart to the left and backward, which occurs secondary to the enlargement of the right ventricle, also contributes to the apparent prominence of the pulmonary artery, as it causes the aortic knob to become less prominent.

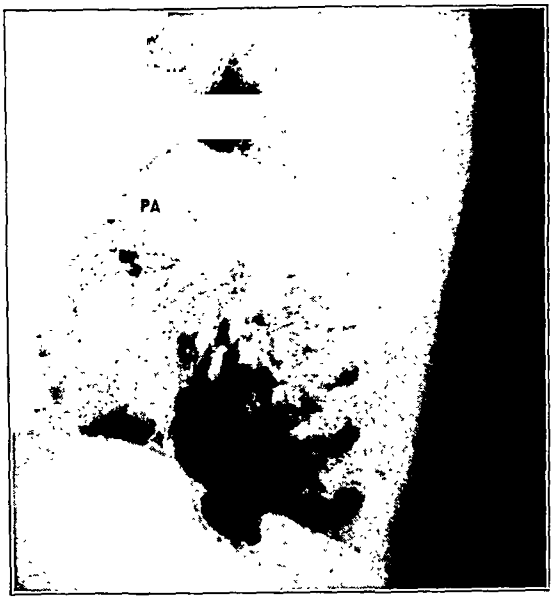

Fig. 4.—Congenital pulmonic stenosis above the pulmonary valve in a patient aged 28 years; left lateral projection. Arrow indicates stenosis, distal to pulmonary semilunar valves. Note dilatation of the pulmonary artery (PA) and its branches, distal to stenosis.

Not invariably present, though often striking, in mitral stenosis is dilatation of the pulmonary trunk and its branches. Figure 6 shows dilatation of the left pulmonary artery in a patient who had clinically established and roentgenographically typical mitral stenosis. We agree that the earliest change in mitral stenosis which can be observed roentgenologically is an enlarged left atrium[10] and have made angiocardiographic observations of normal pulmonary arteries in the presence of enlarged left atria due to mitral stenosis. Disease of the aortic valve in the absence of cardiac failure had no effect on the pulmonary artery in our series. Cardiac failure, regardless of its etiology, may result in dilatation of the bed of the central pulmonary artery as well as in the familiar congestion of the pulmonary vessels.

*Syphilis.*—Syphilis of the pulmonary artery is similar to, less common than and generally accompanied by syphilis of the aorta. The disease may affect the major pulmonary arteries in the form of arteritis not unlike that of the aorta, with intimal thickening and destruction of the elastica. Although overemphasized, syphilitic endarteritis of the lesser branches of the pulmonary artery does occur and may occasion secondary atheromatous changes in the main branches,

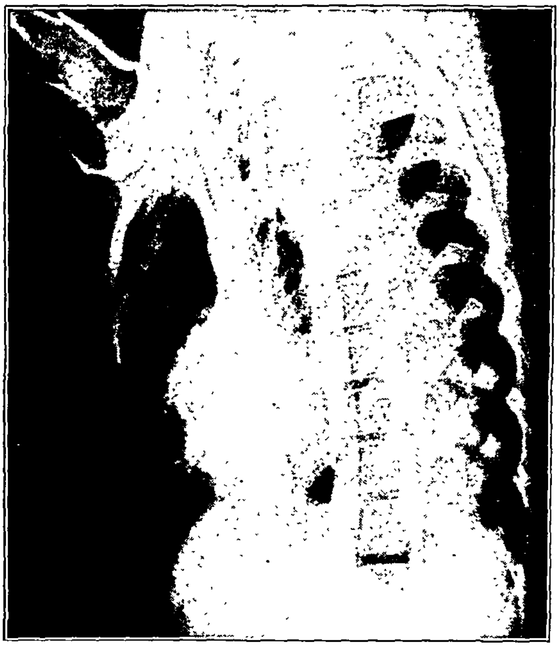

Fig. 5.—Tetralogy of Fallot in a patient aged 9 years; left anterior oblique projection, two seconds exposure. Note simultaneously opacified large right ventricle and small left ventricle and the aorta, which was overriding. The pulmonary artery was decidedly stenotic and did not fill. (Diagnosis confirmed at operation.)

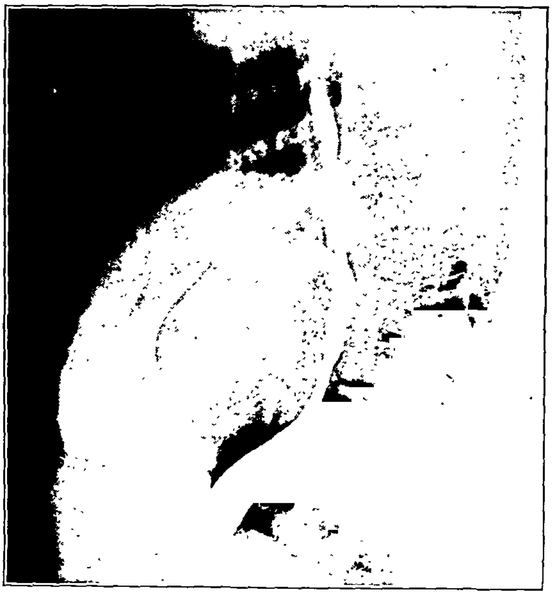

Fig. 6.—Rheumatic mitral stenosis in a patient of 46 years; left lateral projection, with barium in esophagus. Note enlarged right ventricle and dilated pulmonary artery, which are filled with sodium iodomethamate. The enlarged left atrium is outlined in negative contrast.

with ultimate pulmonary hypertension and cor pulmonale.[11] Clinically and roentgenographically, however, syphilis of the pulmonary artery is usually manifested in the form of an aneurysm. Including 2 cases of their own, Boyd and McGavack were able to collect only 35 cases of syphilitic aneurysm of the pulmonary artery or its main branches in which the diagnosis had been proved by autopsy.[12] Angiocardiographic demonstration of aneurysm of the pulmonary artery is convincing. Sussman recently reported an angiocardiographically visualized aneurysm of the pulmonary artery, of presumably syphilitic origin.[13] Figure 7 shows an aneurysm of the pulmonary artery in a patient with clinically and angiocardiographically established syphilitic aortitis. The pulmonary artery or conus arteriosus may be obstructed by a syphilitic dilatation of the ascending aorta. Garvin and Siegel presented results of clinical and pathologic examinations in 3 such cases, which progressed to cor pulmonale and death.[14]

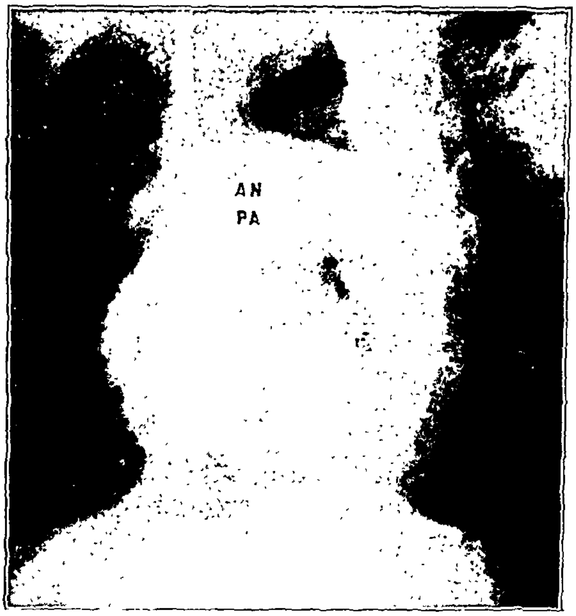

Fig. 7.—Syphilitic aneurysm of the pulmonary artery in a patient aged 60 years; left anterior oblique projection. ANPA, aneurysm of the pulmonary artery and its main branches.

*Pulmonary Heart Disease.*—It is generally accepted that chronic pulmonary disease is the principal cause of cor pulmonale. Robb and Steinberg reported in detail the angiocardiographic observations in a case of chronic pulmonary fibrosis and emphysema,[4f] while Sussman, Steinberg, and Grishman reported similar evidence in 28 cases of pulmonary emphysema.[4g] Although chronic obstructive emphysema is the most frequent cause of chronic cor pulmonale, silicosis, bronchiectasis, tuberculosis, bronchial asthma, kyphoscoliosis or primary sclerosis of the pulmonary artery (Ayerza's disease) may be associated with the changes of pulmonary heart disease. These changes are similar, regardless of the etiology or dynamics involved. We have observed hypertrophy of the right side of the heart associated with emphysema, pulmonary fibrosis, extensive fibrotic pulmonary tuberculosis, bronchiectasis, silicosis, chronic obstruction of the conus arteriosus by aortic aneurysm, kyphoscoliosis and primary sclerosis of the pulmonary artery.

In the presence of chronic pulmonary hypertension, the earliest change observed angiocardiographically was elongation of the pulmonary outflow tract, including both the conus arteriosus and the pulmonary artery, followed by moderate dilatation of the bed of the pulmonary trunk. Concomitant dilatation and hypertrophy of the right ventricle occur, usually causing the pulmonary artery to swing to the left and assume a more prominent position in the left upper border of the heart. Absolute enlargement of the right ventricle is often recognizable, while, in some instances, a bulge of the interventricular septum toward the left has been of help in identifying enlargement of the right ventricle.[4g]

The New York Heart Association requires the presence of "evidence of cardiac insufficiency with marked cyanosis" for the diagnosis of pulmonary heart disease.[15] Rheumatic valvular disease may be diagnosed long before cardiac failure is present, and it would seem logical to proceed similarly in the case of cor pulmonale. The presence of cyanosis should be no more necessary in the diagnosis of cor pulmonale than the presence of calcification of the mitral ring is necessary in the diagnosis of mitral stenosis.

*Other Secondary Abnormalities of the Pulmonary Artery.*—A variety of other intrathoracic abnormalities alter the configuration of the central pulmonary arterial system. Mediastinal or pulmonary tumors, primary or metastatic, may encroach on or distort the main branches of the pulmonary artery. Angiocardiographic evidence of actual stenosis, or occlusion, of a major pulmonary artery due to a tumor is usually evidence that the lesion is advanced and probably inoperable. The detailed vascular pattern in pulmonary tumors is being studied at the time of writing.

Kyphoscoliosis causes stretching and distortion of the cardiovascular structures, often bringing about enlargement of the right side of the heart and dilatation of the pulmonary artery, secondary to obstructive emphysema and extremely inefficient functioning of the lungs. After thoracoplasty and pneumothorax, a decrease in the caliber of the pulmonary artery supplying the collapsed side has been noted repeatedly in our series of cases. After pneumonectomy, a secondary dilatation of the branch of the pulmonary artery supplying the remaining lung has been observed. Such secondary or dynamic dilatation or diminution of the pulmonary artery is comparable to compensatory hypertrophy or atrophy of disuse in general, and is in agreement with the results of studies on the functioning of the lungs.[16] Angiocardiographic visualization of the abnormal pulmonary artery in these conditions is satisfactory and superior to other methods of structural investigation.

Frequently, in the course of conventional roentgenoscopic examination of the chest, prominent shadows are observed in one or both hilar regions and the problem of differential diagnosis arises. Angiocardiography easily differentiates between enlarged hilar vessels and nonvascular structures, such as enlarged hilar lymph nodes or tumors. The identity of rounded hilar shadows and hilar vessels seen end on may be established by visualization with contrast mediums. It may be difficult to distinguish aneurysm of the descending aorta from dilatation of the left main branch of the pulmonary artery without the aid of angiocardiography.

## SUMMARY

A survey of the pulmonary artery and its main branches in normal and abnormal conditions, utilizing the angiocardiographic material and the experience accumulated over an eleven year period, has been presented. The value of angiocardiography in arriving at early and anatomically precise diagnoses of conditions affecting the pulmonary artery has been stressed and illustrated.

Visualization with contrast medium has proved itself indispensable in the diagnosis of congenital cardiac lesions. Angiocardiographic visualization of the pulmonary artery should be utilized in every case of tetralogy of Fallot prior to surgery, in order that surgical method may be correctly planned, unproductive approaches avoided and valuable time saved. No longer need exact anatomic diagnosis of congenital lesions of the heart originate at autopsy. Angiocardiographic evidence of a lesion is often as convincing proof as pathologic examination, and it has the advantage of being applicable to the living patient.

The earliest change observed angiocardiographically in mitral stenosis has been enlargement of the left atrium, followed infrequently with enlargement of the pulmonary artery and the right ventricle. This is in accordance with conventional roentgenoscopic observations. With the aid of angiocardiography, aneurysmal dilatation of the pulmonary artery may now be identified with ease, and data on factors responsible for such dilatations may be clarified. In our series, dilatation of the pulmonary artery was seen to be caused by congenital and acquired diseases of the heart and chest. Congenital lesions included patent ductus arteriosus, septal defects (more pronounced dilatation resulted from interatrial, as opposed to interventricular, defects), idiopathic aneurysmal dilatations, the Eisenmenger complex and pulmonic stenosis. Dilatation of the pulmonary artery and its major branches was also seen in the presence of mitral stenosis, congestive cardiac failure, chronic pulmonary disease and kyphoscoliosis. It is suggested that the diagnosis of pulmonary heart disease can be made far in advance of the appearance of cyanosis, not only with angiocardiographic methods but also with conventional roentgenoscopy, and it is suggested that the official criteria for the diagnosis of this condition are in need of modification.

The value of angiocardiography in the preoperative diagnosis of pulmonary and mediastinal tumors has been discussed. It is often possible to establish angiocardiographically the inoperability of tumors which have spread to the mediastinum and altered the configuration of the great blood vessels. Changes occurring in the bed of the pulmonary artery after artificial pneumothorax or pneumonectomy have been demonstrated and are in accordance with physiologic principles.

## CONCLUSIONS

While conventional roentgenography of the pulmonary artery is often difficult, inadequate and anatomically vague, angiocardiographic visualization is simple, adequate and [illegible] cise. The angiocardiographic configuration of the normal pulmonary artery is outlined, as are the changes present in cardiac, mediastinal and pulmonary disease. These changes are considered academically and from the standpoint of improved diagnosis. Angiocardiography is indispensable in the preoperative investigation of congenital cardiac disease and facilitates exact anatomic diagnosis, often otherwise impossible during life.

## ABSTRACT OF DISCUSSION

Dr. Harry M. Weber, Rochester, Minn.: This might well be considered a decennial presentation, for it was at the session of the American Medical Association in San Francisco in June 1938, before the Section on Pharmacology and Therapeutics, that Dr. Steinberg and Dr. Robb made their first report on the practical method they had developed of visualizing the chambers of the heart, the pulmonary circulation and the great blood vessels in man. As Dr. Dotter pointed out, angiocardiography is practically indispensable in the diagnosis of certain cardiovascular abnormalities, especially congenital ones for which, in recent years, a satisfactory surgical therapy has been developed. I refer especially to the diagnosis of the tetralogy of Fallot and its accurate differentiation from the Eisenmenger complex, the clinical indications of which are so similar. Frequently, too, the exact anatomic situation may be demonstrated with angiocardiography, demonstrated as in patent ductus arteriosus and in coarctation of the aorta, conditions in which, with conventional clinical and roentgenologic methods, diagnosis may be made but the exact pathologico-anatomic situation remains unknown, or at least poorly estimated, preoperatively. Dr. Dotter and Dr. Steinberg are now interested in applications of the method and in certain mechanical improvements to facilitate roentgenography at the proper intervals after the contrast solution is administered. I wish to thank Drs. Steinberg and Dotter for this excellent and instructive presentation. It has not only enlarged our diagnostic vista, but also done much to clarify and correct our notions about the use and limitations of our more conventional roentgenologic procedures in cardiovascular diagnosis.

Dr. Fred J. Hodges, Ann Arbor, Mich.: Having read the paper and having seen in the original the superb illustrations that Dr. Dotter prepared for us, it is too bad that they were shown under very trying conditions. His films must be studied at some length in order to appreciate their true worth. The paper by Drs. Dotter and Steinberg goes far beyond earlier contributions in the field of angiocardiography. This morning we have been shown broad and highly practical applications of the technic. In particular, the utility of angiocardiography in the study of acquired heart disease is promising. To be able to identify cor pulmonale in advance of late cardiac failure is distinctly worthwhile. Dr. Dotter's illustrations represent complete mastery of the technical procedures which, of necessity, are of an exacting type. At my institution there has been constructed a considerably modified, multiple exposure x-ray camera, based on the principle introduced by Dr. Hans Jarre, of Detroit, many years ago. This apparatus makes it possible to prepare a succession of direct roentgenograms on a continuous strip of film, 8 inches wide. Frames for individual exposures are 8 by 10 inches. Exposures can be made at the rate of five per second. Technical experience at the institution thus far is meager, but I am convinced that the apparatus will be of considerable use in cardiography and that, once there is thorough familiarity with its technic, angiocardiography will find frequent applications in daily practice. Experimental runs on dogs, as well as results obtained for the relatively few patients examined thus far, have indicated that smaller, rather than larger amounts of opaque material would be desirable in demonstrating the relationships of cardiovascular structures.

I should like to ask Dr. Dotter if, in his experience, it is desirable or necessary to inject as much as 40 cc. of the contrast medium.

Dr. Leo Rigler, Minneapolis: After seeing this beautiful demonstration, I am reluctant to introduce any discordant note, but I wish to emphasize that, while angiocardiography certainly is a method of study which permits us to learn a great deal about congenital heart diseases and diseases of the pulmonary arteries, one must not be overwhelmed by the brilliant detail presented in these films and develop an inferiority complex about conventional methods of diagnosis. I think it is possible, particularly in the noncyanotic types of congenital heart disease, to make an accurate diagnosis without angiocardiography in the overwhelming majority of cases if all the diagnostic factors, including, of course, meticulous roentgenologic studies, are considered. In cyanotic heart disease, I believe that angiocardiography may well be necessary in a much larger percentage of the cases. I was most interested in Dr. Dotter's statement about pulmonic stenosis, and should be gratified to know the basis for his impression that isolated pulmonic stenosis is not rare. My only experience, in a large series of autopsies in cases of congenital heart disease of all kinds and descriptions, is that isolated pulmonic stenosis of the type found in the tetralogy of Fallot is very rare. This is of some importance in the question of whether true pulmonic stenosis, without associated defects and, at least, in its relatively early stages, actually can produce cyanosis. I should like to reemphasize Dr. Dotter's criticism of the criteria which have been given for the diagnosis of cor pulmonale. It has been my experience that the diagnosis of cor pulmonale can be made in a great many cases long before right heart failure has occurred. If one carefully studies cases of bronchial asthma, silicosis or tuberculosis, the enlargement of the right side of the heart, first indicated by enlargement of the pulmonic artery, becomes apparent long before the symptoms of actual failure, such as cyanosis and ascites, appear.

Dr. J. E. Miller, Dallas, Texas: Dr. Dotter has indicated that his cases of the Eisenmenger complex were not amenable to aortic-pulmonary anastomosis. I have 4 or 5 patients in whom I have made this diagnosis from angiocardiography, and the same may be true of them. In 1 of the patients, however, where most of the contrast material went into the pulmonary artery, instead of the aorta, the clinicians were not entirely satisfied that my impression of the Eisenmenger complex was correct. The patient was operated on, with the plan of measuring pressures in the pulmonary artery. The clinicians had indicated that anastomosis would be done provided the pressure was less than 350 mm. of water. The measurements indicated that the pressure was 300 mm. of water, plus or minus 20. The anastomosis was made, and the result was excellent. Since I have other patients with the same angiocardiographic diagnosis, there will be a clinical reevaluation; perhaps some of them will be operated on. We should not say that anastomosis is not applicable when the diagnosis of Eisenmenger's complex has been made angiocardiographically.

Dr. Charles T. Dotter: We have seen at least 2 cases of pulmonic stenosis in adults in whom we were unable to demonstrate any other cardiovascular lesion. We believe it a more common condition than formerly recognized and anticipate that studies employing catheterization of the heart will bear this out. In our experience, the diagnosis of Eisenmenger's syndrome should be made angiocardiographically only when a large, dilated, nonstenotic pulmonary artery can be demonstrated. The decision regarding operative intervention rests solely upon the shoulders of the surgeon. In closing, may I comment upon the undeserved reputation which angiocardiography has gained, namely, that it is a difficult procedure. It can be accomplished with very little special equipment, making use of a standard cassette with which one obtains only two films during an injection. All the films which you have seen today were made in that manner. For the other details of technic, may I refer you to the papers of Drs. Robb and Steinberg, published in 1938 and 1939.[2] The details have changed very little since then. I believe that angiocardiography will grow to be a commonplace method of examination, employed in all hospitals and in the hands of many radiologists.

# RETROLENTAL FIBROPLASIA

## Incidence in Different Localities in Recent Years and a Correlation of the Incidence with Treatment Given the Infants

V. EVERETT KINSEY, Ph.D.
and
LEONA ZACHARIAS, Ph.D.
Boston

Retrolental fibroplasia (R. L. F.) is an ocular disease usually associated with prematurity and usually affecting both eyes. The most conspicuous diagnostic sign is the presence of a membrane, often vascularized, situated behind the crystalline lens. The presence of blood vessels in the membrane serves to differentiate retrolental fibroplasia from congenital cataract. The affected eye may be smaller than normal, the anterior chamber shallow and the ciliary body abnormally serrated. Secondary changes, such as synechiae, glaucoma and iritis, frequently develop. The disease is rarely, if ever, seen at birth but develops when the infant is between 1 and 5 months of age. It has been seen to start as a dilatation of the retinal vessels followed by exudative retinitis and subsequent retinal detachment.[1]

Retrolental fibroplasia was first associated with prematurity by Terry[2] in 1942. Since then there have been indications that the incidence has increased more in some localities than in others. The apparent increase in the frequency of the disease in recent years cannot be explained by the statement that the condition in a significant number of cases was formerly undiagnosed and therefore missed[3] or that a significantly greater proportion of premature infants survives now than in 1942.[4] To date, no satisfactory theory of the cause of retrolental fibroplasia has been proposed. It seems likely, however, that if it were demonstrated that the incidence of the disease were actually increasing, or that the incidence varied significantly from place to place, the possible number of explanations would be greatly reduced. Moreover, it might be feasible, from a knowledge of the incidence in any one locality over a period of years, or in various localities, to correlate the incidence with some factor associated with mother or infant at one particular time or place. Accordingly, studies were made of the number of premature infants born in particular hospitals in various localities, in whom retrolental fibroplasia did or did not develop. The results to be reported show that the incidence, at least in some localities, has increased and that this increased incidence correlates positively with certain treatment given to the infant, although,

---

From the Departments of Ophthalmology and Obstetrics and the Howe Laboratory of Ophthalmology, Harvard Medical School; the Massachusetts Eye and Ear Infirmary; the Boston Lying-in Hospital, and the Providence Lying-in Hospital. Supported by a grant from the Foundation for Vision for the study of retrolental fibroplasia.

Mrs. Harriet D. Parish and the staffs of the record rooms and social service departments of the Boston Lying-in and Providence Lying-in hospitals gave assistance in this study; Drs. Stewart Clifford and Clement Smith gave advice and suggestions in reporting the results of the study and outlining the new vitamin and iron medication schedule to be used at the Boston Lying-in Hospital.

1. Owens, W. C., and Owens, E. U.: Retrolental Fibroplasia in Premature Infants, Tr. Am. Acad. Ophth. **53**: 18-38 (Sept.-Oct.) 1948.

2. Terry, T. L.: Extreme Prematurity and Fibroblastic Overgrowth of Persistent Vascular Sheath Behind Each Crystalline Lens, Am. J. Ophth. **25**: 203-204 (Feb.) 1942.

3. *The fact that cases of retrolental fibroplasia were not recognized* in former years cannot alone account for the present apparent rise in incidence, because the number of children born since 1942, in certain localities at least, whose vision is seriously impaired by retrolental fibroplasia far exceeds the number of cases of blindness occurring in former years which could possibly be attributed to this condition.

4. The survival rate of premature infants at the Boston Lying-in Hospital has not i [illegible] the past sixteen years. Values reported for [illegible] C.: Premature Infant, Children's Bureau [illegible] Department of Labor, Children's Bureau, 1948) suggest that any increased survival rate is small compared with the apparent increase in incidence of retrolental fibroplasia.

as indicated later, this correlation does not constitute proof of causal relation between incidence and treatment.

### PREVIOUS STUDIES

Previous reports of the incidence of retrolental fibroplasia (with the exception of the report of Owens and Owens[1] at the Johns Hopkins Hospital in Baltimore and that of Gilger[5] at the Cincinnati General Hospital, to which detailed reference will be made later) have been preliminary in nature. Ingalls,[6] quoting a personal communication from Clifford and Allers, stated that at the Boston Lying-in Hospital, between 1938 and 1945, the incidence of the disease for 254 infants, weighing less than 4 pounds (1,814 Gm.) at birth, is 13 per cent. He mentioned, however, that 4 of the infants with retrolental fibroplasia weighed more than 4 pounds at birth, in which case the incidence rate for infants weighing less than 4 pounds at birth appears to be approximately 11 per cent. He pointed out, also, that the estimate is probably conservative because of "missed" cases. The number of babies successfully investigated is not given, and Ingalls concluded that the stated incidence rate must be considered approximate.

Clifford and Weller[7] (quoting a personal communication from Allers) said that the incidence in the same nursery in Boston was 23 per cent for infants weighing between 2 and 3 pounds (907 and 1,361 Gm.) at birth. The number of infants on which this figure is based and the period of time covered are not given.

Others who have studied retrolental fibroplasia, including Krause[8] and Reese and Payne,[9] have not investigated the relative frequency of the disease in children born prematurely, although Krause reported that it has occurred in 1 out of 4,000 births at the Chicago Lying-in Hospital. The period covered by the data is not given.

### METHODS

Inquiries[10] were sent to parents or guardians of all infants born at the Boston Lying-in Hospital and Providence Lying-in Hospital who weighed 4 pounds or less at birth, to establish the present condition of their eyes. Responses were obtained concerning 93 and 95 per cent of all infants in these two locations, respectively. When an ocular defect was reported, the children were seen by an ophthalmologist who gave the diagnosis in any cases of retrolental fibroplasia. The information used in correlating incidence of the disease and factors relating to the mothers and infants was taken from the hospital records, and frequently additional information was obtained from the mothers and pediatricians concerning the treatment of the infant after discharge from the hospital.

### RESULTS

The results of the study for the Boston Lying-in and Providence Lying-in hospitals and those of Gilger for Cincinnati are shown in a series of 9 graphs in which the data are presented for each year studied. The first figure for each place shows the birth weights of infants in whom retrolental fibroplasia developed, plotted as a scattergram. The second figure presents in percentage the incidence of the disease for all of the children and the incidence, separately, for those infants weighing less than 3 pounds and those who weigh between 3 and 4 pounds at birth. The third figure shows the actual number of cases of retrolental fibroplasia, the number of children in whom this disease did not develop and, indicated by a line above the blocks, the number of children about whom no information could be obtained.

* *Normal in all tables indicates simply the absence of retrolental fibroplasia.*

† It will be observed that the data given for the Chicago hospital (Michael Reese Hospital) cover a twenty-five year period. The ages of the 5 patients with retrolental fibroplasia were 2, 3, 5, 7 and 16 years (4 females, 1 male), indicating that the incidence of the disease has been and still remains low.

The data from the other cities are not presented graphically because either the number of cases of retrolental fibroplasia was too small or the period of time covered in the studies was too short. They are included, however, in this report (table 1), since they represent the only available information at this time on the incidence of this disease.

*Boston.*—There were 372 infants weighing 4 pounds or less at birth and surviving six months or more, who were born at the Boston Lying-in Hospital during the years 1938 through 1947. Of these, it was found that retrolental fibroplasia had developed in 53 and had not developed in 298; 21 could not be located. In 44 of the cases of retrolental fibroplasia, both eyes were affected; in 9, one eye only was affected. From figures 1, 2 and 3 it is evident that the incidence of the disease had increased during the second five years of the period studied (1943 through 1947), and that this increase is accounted for chiefly by an increase in cases among the heavier infants (3 to 4 pounds). Figure 3 shows that only 1 case of retrolental fibroplasia occurred in 102 premature infants weighing between 3 and 4 pounds at birth (1.0 per cent) prior to 1943, whereas in the same weight group there were 33 cases in 162 premature infants (20 per cent) in the years 1943 through 1947. The incidence during the same two periods in infants born in this hospital who weighed less than 3 pounds at birth (table 1) was 20.5 and 26.3 per cent, respectively. The year to year fluctuation in the incidence of the disease in the lighter group of infants (figure 3) may be explained by the small number of infants in this weight group.

[10] The data for the New York Hospital were collected by Dr. Lewis Fraad, and the diagnoses were made under the supervision of Dr. John McLean of the Department of Ophthalmology of the Cornell Medical School. The information concerning the Cincinnati General Hospital and the Hartford Hospital was supplied by Dr. Anita P. Gilger and Dr. A. C. Unsworth, respectively, and will be reported by each in detail elsewhere. The study at the Johns Hopkins Hospital in Baltimore was made by Drs. William and Ella Owens The data concerning the Colorado General Hospital in Denver were supplied by Dr. Lula O. Lubchenco and Dr. Harry H. Gordon; those for the Michael Reese Hospital in Chicago, by Dr. Julius Hess and Miss Evelyn C. Lundeen; those for Birmingham, England, by Dr. V. Mary Crosse of the Public Health Department of Birmingham.

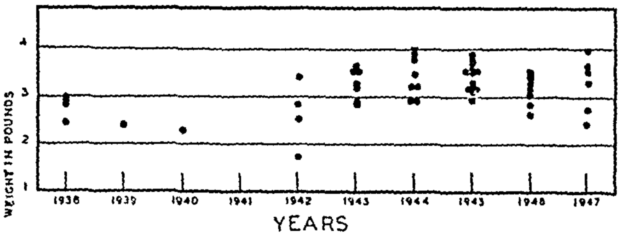

Fig. 1.—Birth weights of premature infants in whom retrolental fibroplasia developed who were born at the Boston Lying-in Hospital.

*Providence.*—There were 246 infants weighing less than 4 pounds at birth and surviving six months or more, who were born at the Providence Lying-in Hospital during the years 1941 through 1947. Of these, it was found that retrolental fibroplasia had developed in 16 and had not developed in 218; 12 could not be located. In 14 of the cases of retrolental fibroplasia both eyes were affected; in 2, one eye only was affected. Figure 4 shows that, unlike the situation at the Boston hospital, the retrolental fibroplasia occurred in the 3 to 4 pound weight group with approximately the same frequency throughout the period of study. Figure 5 shows that the total incidence of the disease has not varied significantly throughout the eight year period. The high incidence observed in the light weight group during the years 1942 through 1944 is not significant because of the small number of infants in this group (fig. 6).

*Cincinnati.*—There were 156 infants weighing less than 4 pounds at birth, presumably living at the time the survey was made, who were born at the Cincinnati General Hospital during the years 1943 through 1947. Of these, it was found that retrolental fibroplasia had developed in 7 and not in 89; 60 could not be located.

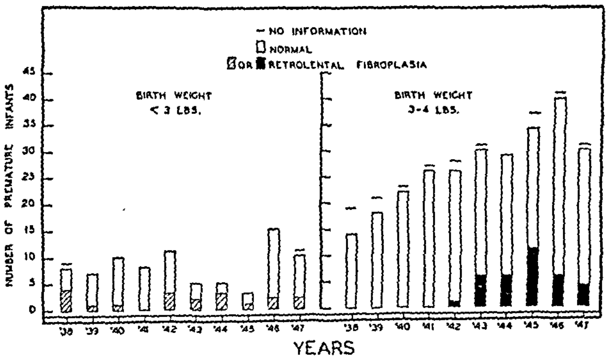

Fig. 2.—The number of premature infants born at the Boston Lying-in Hospital (top line), the number of cases of retrolental fibroplasia (cross hatch for the birth weight group under 3 pounds and solid blocks for the birth weight group 3 to 4 pounds) and the number of premature infants known to be normal with respect to retrolental fibroplasia (open blocks).

The number of cases of retrolental fibroplasia in children born at this hospital is too small to permit any conclusions with regard to distribution by years.

*Other Cities.*—The data regarding the incidence of retrolental fibroplasia for other cities are summarized and presented in table 1, along with a similar condensation of the data for the three cities already reported. The table shows that the incidence in the infants weighing less than 3 pounds at birth is higher in every location (where any cases of retrolental fibroplasia exist) than it is in the group weighing 3 to 4 pounds at birth. It shows also that there is a considerable variation in the incidence in different localities.

The data thus far presented suggest that the incidence of retrolental fibroplasia has increased in recent years, particularly in the 3 to 4 pound weight group in the Boston hospital. The question arises as to whether any particular factor or factors associated with the mothers or infants can be correlated with the increased incidence of the condition. Those factors affecting the mothers or infants may be divided into two classifications. The first (tables 2 through 13) includes those factors affecting some mothers or some infants throughout the ten year period studied. The second includes those factors which either were absent entirely or varied significantly from one part of the study period to another, but which applied to all cases, once initiated.

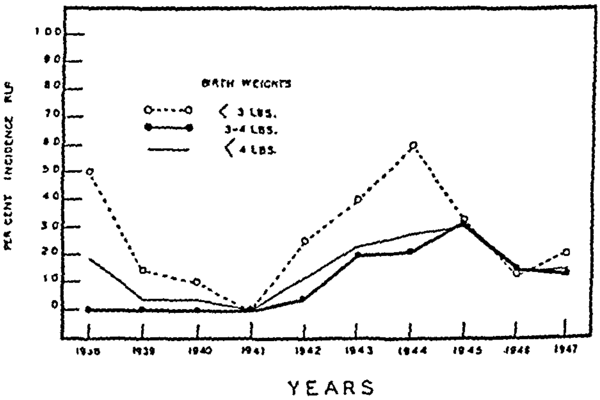

Fig. 3.—The incidence of retrolental fibroplasia in premature infants born at the Boston Lying-in Hospital.

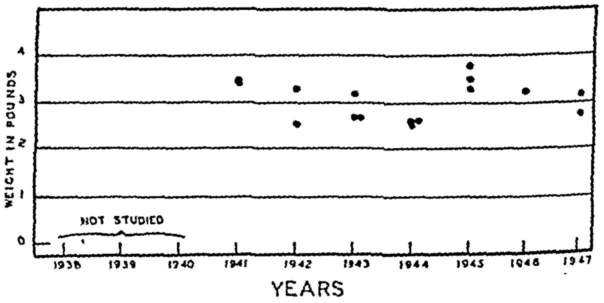

Fig. 4.—Birth weights of premature infants in whom retrolental fibroplasia developed who were born at the Providence Lying-in Hospital.

In the first classification it is possible to determine whether the incidence of retrolental fibroplasia in any particular group is different from that in the total group. The factors considered are:

Parity (table 2)
Age of mother (table 3)
Rh type (table 4)
Type of delivery (table 5)
Analgesic administered (table 6)
Anesthesic administered (table 7)
Causes of prematurity (table 8)

Single or multiple births (table 9)
Sex of the infant (table 10)
Presence of congenital abnormalities (table 11)
General information (table 12)
Miscellaneous (table 13)

There appears to be a significant correlation between the incidence of retrolental fibroplasia and only two of the aforementioned factors. The first of these is seen in table 2, which shows that the incidence of retrolental fibroplasia in offspring of primiparous women (45 per cent of the total) was 9.5 per cent compared with 19.7 per cent in those of multiparous women. This difference in incidence may be said to be significant, since the probability that it would occur by chance is much less than 1 in 100. The number of cases involved in each parity group above 1, taken separately, is too small to determine whether the incidence rises progressively with parity.

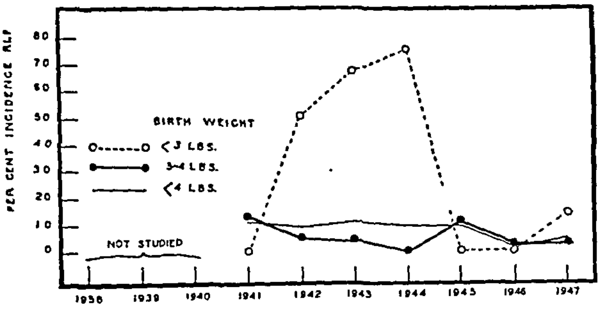

Fig. 5.—The incidence of retrolental fibroplasia in premature infants born at the Providence Lying-in Hospital.

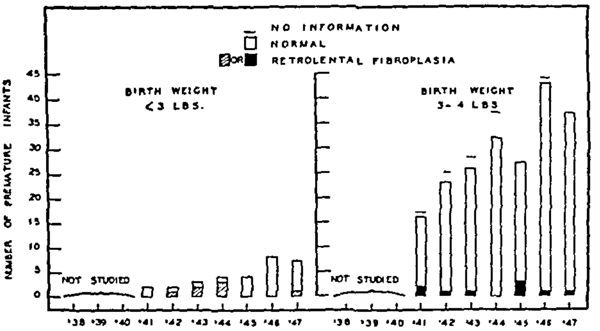

Fig. 6.—The number of premature infants born at the Providence Lying-in Hospital (top line), the number of cases of retrolental fibroplasia (cross hatch for the birth weight group under 3 pounds and solid blocks for the birth weight group 3 to 4 pounds) and the number of premature infants known to be normal with respect to retrolental fibroplasia (open blocks).

The second instance of possibly significant correlation is seen in table 12, which shows that infants in whom retrolental fibroplasia subsequently developed remained in the nursery, water jacket incubator and in oxygen for longer periods than the infants in whom retrolental fibroplasia did not develop. This suggests that the general health of the infants in whom retrolental fibroplasia subsequently developed may have been poorer than of those whose eyes remained normal, or possibly that the latter were larger infants requiring a shorter stay in the hospital.

The distribution of cases of retrolental fibroplasia according to sex is also of possible significance. Table 10 shows that the disease occurs more frequently in male (14.0 per cent) than in female (9.2 per cent) subjects. The probability that this distribution would occur by chance is between 1 in 10 and 1 in 20. The distribution by sex at the Boston hospital was approximately constant from year to year, except for 1945, in which year all 12 cases of retrolental fibroplasia occurred in male subjects. The probability that this would occur by chance, considering the average incidence in all of the years in male and female subjects in the Boston hospital, is less than 1 in 1,000,000. We are unable to account for the distribution by sex in this year, or for the much higher incidence observed in 1945 compared with that in the years 1943, 1944, 1946 and 1947.

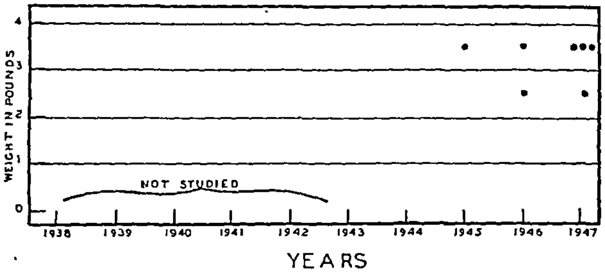

Fig. 7.—Birth weights of premature infants in whom retrolental fibroplasia developed who were born at the Cincinnati General Hospital.

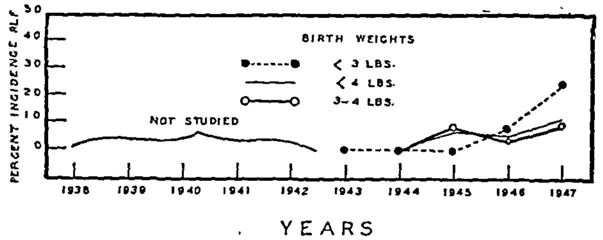

Fig. 8.—The incidence of retrolental fibroplasia in premature infants born at the Cincinnati General Hospital.

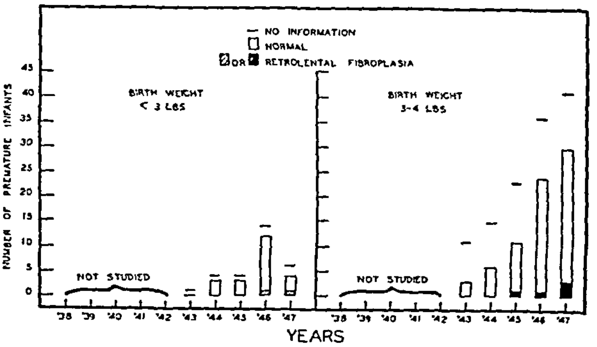

Fig. 9.—The number of premature infants born at the Cincinnati General Hospital (top line), the number of cases of retrolental fibroplasia (cross hatch for the birth weight group under 3 pounds and solid blocks for the birth weight group 3 to 4 pounds) and the number of premature infants known to be normal with respect to retrolental fibroplasia (open blocks).

Gilger (Cincinnati), who has similarly attempted to correlate incidence with factors affecting mothers or infants, found no correlation between the incidence of the disease and the age of the mother, frequency of uterine bleeding, virus infections during pregnancy, chronic illness during pregnancy, causes of prematurity or race. She found, as we did, a probable positive correlation between the parity of the mothers and the incidence of retrolental fibroplasia, since all 7 of the cases of the condition which she reports occurred in infants of multiparous mothers. The probability that this would occur by chance is 1 in 10. She did not investigate the length of stay in the hospital and other such factors.

The use of the analgesic meperidine hydrochloride was the only factor of those thus far considered in which there was any appreciable variation in frequency of administration in one part of the period investigated compared with another. This drug was used more frequently in the last five year period and was administered to 77 mothers in 166. The incidence of retrolental fibroplasia in infants born to mothers receiving meperidine hydrochloride was 23.5 per cent compared with an incidence of 19 per cent in infants whose mothers did not receive the drug. This difference is not significant.

The second classification, viz., the factors which changed from one part of the 1938 through 1947 period compared with another part, and which once initiated affected all infants, will now be considered. As mentioned previously, the most striking instance of increased incidence (fig. 2) occurred during the second half (1943 through 1947) of the ten year period in infants weighing between 3 and 4 pounds. Since any correlation between treatment and incidence might be expected to be most evident in this group in which the increase in incidence was most apparent, the following data are concerned with this birth weight group only (3 to 4 pounds). Examination of the hospital records showed that the treatment of the infants varied significantly with time in three respects only: first, administration of a multiple vitamin preparation in which the fat-soluble vitamins are made miscible with water; secondly, administration of iron in greatly increased quantities, and thirdly, more frequent administration of oxygen.

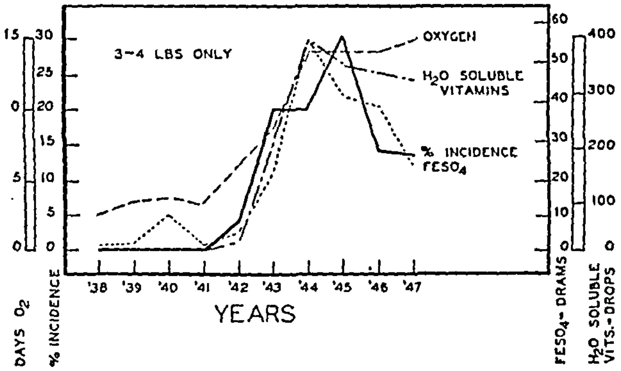

Fig. 10.—Correlation between the incidence of retrolental fibroplasia in premature infants born at the Boston Lying-in Hospital, and the administration of oxygen, ferrous sulfate (1 dram contains 1 grain, 65 mg. iron sulfate) and vitamin supplements given in a water-miscible form.

To determine whether there was a significantly positive correlation between the increased incidence and the use of any or all of these three agents, the average actual amount administered per infant per hospital stay was plotted along with the incidence of the disease for the same period. This method of representing the data is necessarily arbitrary, but since all three forms of treatment were used for essentially all of the infants, this method of averaging seems to represent a valid method for comparing change in incidence with change in quantity of the agent administered. From figure 10 it may be seen that the incidence rises along with the total amount of the water-miscible vitamin preparation and the total amount of iron given. The graphs also show that the maximum quantity of the water-miscible vitamin preparation and iron given and the maximum incidence of retrolental fibroplasia do not correspond precisely. The correlation between rise in incidence and dosage is less striking for oxygen than for the water-miscible vitamin preparation and for iron.

Table 2.—*Parity,* Boston Lying-in Hospital*

| Para | Normal Children | Children with R.L.F. | Incidence, Percentage |
|---|---|---|---|
| 1 | 143 | 15 | 9.5 |
| 2 | 67 | 13 | 16 |
| 3 | 33 | 13 | 28 |
| 4 | 20 | 4 | 17 |
| 5 | 13 | 4 | 24 |
| 6 | 5 | 0 | 0 |
| 7 | 1 | 1 | 50 |
| 8 | 5 | 1 | 17 |
| 9 | 4 | 0 | 0 |
| 10 | 1 | 0 | 0 |
| Over 10 | 1 | 1 | 50 |
| Unreported | 5 | 1 | 17 |
| Total multiparas | 150 | 37 | 19.7 |
| Total | 298 | 53 | 15.1 |

* The percentage of the total group of premature infants whose mothers were primiparas does not differ significantly from the percentage of the total number of term babies born of primiparous mothers. This was true also for mothers who gave birth to their second and third, fourth and fifth, sixth child or more.

Additional information concerning the possible correlation between the three forms of treatment considered herein and the incidence of retrolental fibroplasia can be obtained by comparing the treatment with respect to these three items and the incidence of the condition in other localities where sufficient data regarding treatment are available.

Table 3.—*Age of Mother, Boston Lying-in Hospital*

| Years | Normal Children | Children with R.L.F. | Incidence, Percentage |
|---|---|---|---|
| 16-25 | 89 | 14 | 14 |
| 26-35 | 146 | 27 | 16 |
| 36-45 | 52 | 10 | 16 |
| Unreported | 11 | 2 | 15 |
| Total | 298 | 53 | 15.1 |

Table 4.—*Rh Type,* Boston Lying-in Hospital*

| Type † | Normal Children | Children with R.L.F. | Incidence, Percentage |
|---|---|---|---|
| Rh + | 67 | 16 | 19 |
| Rh — | 13 | 5 | 28 |

* Years 1945, 1946 and 1947 only.

† In the white population the distribution according to Rh type is 85 per cent Rh positive and 15 per cent Rh negative. The distribution found here in normal persons is 84 per cent Rh positive and 16 per cent Rh negative, and the distribution in infants with retrolental fibroplasia is 76 per cent Rh positive and 24 per cent Rh negative. In this small sample there is no deviation from the normal either with respect to the normal infants or those in whom retrolental fibroplasia developed.

Table 14 (3 to 4 pound weight group only) presents data concerning the administration of water-miscible vitamins[11] and iron given infants in the hospitals studied in other cities in comparison with that given at the Boston hospital. For comparative purposes in the table, the quantities are listed as zero when not given, and higher or lower than the middle range of quantities used at the Boston hospital.

From this table it can be seen that the incidence is 1 per cent or less in those hospitals in which low doses of iron were given either without vitamins in water-miscible form (Boston 1938 through 1942, New York, Birmingham) or with vitamins in this form in low dosages (Baltimore). The incidence is intermediate (between 1 and 20 per cent) in those hospitals in which iron or the amount of water-miscible vitamin preparation used is high (Cincinnati and Providence, group 1, respectively). These data, therefore, show that in cities other than Boston there is also some degree of positive correlation between the incidence of retrolental fibroplasia and the quantity of vitamins given in a water-miscible form or the amount of iron administered. A possible exception to this correlation may be seen from the second group at Providence, where no water-miscible vitamins were administered, but the incidence of retrolental fibroplasia was 4 per cent—an intermediate value.[12] In evaluating the results of such a comparison it is necessary to keep in mind that the regimen may be altered after the infant is sent home. Accurate information concerning home care is difficult to obtain.

Table 5.—*Type of Delivery, Boston Lying-in Hospital*

| Type | Normal Children | Children with R.L.F. | Incidence, Percentage |
|---|---|---|---|
| Breech | 61 | 12 | 17 |

| Pentobarbital sodium | 35 | 2 | 5 |
| Pantopon * | 31 | 7 | 18 |
| Paraldehyde | 16 | 5 | 24 |
| Scopolamine | 147 | 29 | 16 |
| "Seconal sodium" (sodium 5-allyl-5-[1-methylbutyl] barbiturate) | 112 | 21 | 16 |
| Average incidence | | | 15.1 |

* A proprietary preparation containing the total opium alkaloids in the form of soluble hydrochlorides.

We believe that, so far as the factors cited herein may operate to increase the incidence of retrolental fibroplasia, they do so indirectly and not through a direct toxic effect. This belief is supported by the observation that the incidence of the condition in infants under 3 pounds was much less influenced by the presence or absence of these factors from one locality to another, although the incidence was higher than in the heavier infants (3 to 4 pounds). One may suppose that, all other factors remaining constant, an added influence of some kind may be necessary before retrolental fibroplasia develops in any significant number of the heavier infants. The primary mechanism, however, presumably is the same in both weight groups.

Table 7.—*Anesthetic Administered, Boston Lying-in Hospital*

| Type | Normal Children | Children with R.L.F. | Incidence, Percentage |

| Total | 259 | 42 | 14.0 | 337 | 34 | 9.2 |

Some comment is in order regarding the difference between the administration of vitamins in water-miscible form and in other forms. Lewis and his co-workers[13] and Clifford and Weller[7] have shown that the absorption of vitamin A by premature infants when the vitamin is given in a water-miscible form is much higher than it is from an oil-soluble preparation.[14] An infant, therefore, may be capable of absorbing more vitamin A from a water-miscible preparation of 5,000 units of vitamin A than from an oil-soluble preparation of 15,000 units. The water-soluble vitamins presumably are equally well absorbed whether administered in water or accompanying vitamins A and D in the water-miscible form. If, then, the administration of vitamins in a water-miscible form plays a part in increasing the incidence of retrolental fibroplasia, vitamins A or D are probably the ones involved. Since the solvent of the water-miscible preparation used in Boston has been changed several times during the period in which it was used, without a significant change in the incidence of retrolental fibroplasia, it is presumably innocuous. In all the hospitals not using the water-miscible preparation, vitamin A was administered in doses of about 15,000 units per day in an oil preparation, except in Boston in the years 1938 through 1942 when no vitamin A was given.

---

[11] Each drop of the standard preparation used at the Boston hospital provided on the average: vitamin A, 500 units; thiamine, 0.1 mg.; riboflavin, 0.1 mg.; ascorbic acid, 5 mg.; vitamin D, 100 U.S.P. units, and niacinamide, 0.5 mg.

[12] Two of the 4 children with retrolental fibroplasia in Hartford (table 1) were also known never to have received iron or vitamins in a water-miscible form. Data are not available at present concerning treatment administered the children in this group in whom retrolental fibroplasia did not develop.

[13] Lewis, J. M., Bodansky, O., Birmingham, J., and Cohlan, S. Q.: Comparative Absorption, Excretion, and Storage of Oily and Aqueous Preparations of Vitamin A, J. Pediat. 31:496-508 (Nov.) 1947.

TABLE 11.—*Presence of Congenital Abnormalities, Boston Lying-in Hospital*

| Abnormalities | Normal Children | Children with R.L.F. | Incidence, Percentage |

| Average period in water jacket incubator | 12 | 19 |
| Average period in oxygen | 12 | 21 |

The use of cow's or breast milk for feeding in various localities is difficult to correlate with the incidence of retrolental fibroplasia, since in many hospitals the use of breast milk varies so much with the available supply. Nevertheless, from the data which are available the incidence of this condition does not appear to correlate with the differential use of cow's and breast milk.

## CONCLUSIONS

In certain areas the incidence of retrolental fibroplasia has increased significantly in recent years. In Boston, where the data are most complete, the rise in incidence was found chiefly in the 3 to 4 pound (1,361 to 1,814 Gm.) weight group. The greater frequency of retrolental fibroplasia correlates with several changes in treatment of premature infants; i. e., use of vitamin supplements in water-miscible form and increased use of iron. While a positive correlation between rise in incidence of the disease and change in treatment does not constitute proof of any causal relation between the two, nevertheless it is suggestive that the medication used may be of etiologic significance.

To test this possibility, we, in conjunction with the staffs of the Boston Lying-in and certain other hospitals, are planning to investigate the effect on the incidence of retrolental fibroplasia of omitting the iron and also the multiple vitamin preparation in water-miscible form. It is planned to withhold the iron until the premature infant is between 2 and 3 months of age and substitute for the multiple vitamin preparation vitamin D alone, in a water-miscible form (1,000 units daily). In addition, the diet will be supplemented with 50 to 100 mg. of vitamin C daily. No vitamin A or vitamin B-complex will be given. The results of this study will be made available as soon as a sufficient number of infants has been tested to permit statistically valid conclusions concerning the true role of the aforementioned forms of treatment in producing retrolental fibroplasia.

This study has been concerned wholly with premature infants whose birth weights were less than 4 pounds (1,814 Gm.). The incidence of retrolental fibroplasia in heavier premature infants and in term babies has not been investigated, but, from the number of known cases of the disease in such infants, it must be extremely low. Before one draws inferences regarding possible harmful effects from the use of water-miscible vitamin preparations or iron in treating heavier premature infants or term babies, one should consider these facts.

TABLE 13.—*Miscellaneous Factors, Boston Lying-in Hospital*

| Factor | Normal Children | Children with R.L.F. | Incidence, Percentage |
|---|---|---|---|
| Complete blood cell count (baby) | 99 | 17 | 15 |
| X-ray (baby) | 67 | 13 | 16 |

* The quantities are listed as zero when not given, and higher (H) or lower (L) than the middle range of quantities used at the Boston hospital.

---

[14] The use of the vitamin supplement in water-miscible form was inaugurated at the Boston Lying-in Hospital in 1943 to increase the amount of vitamin A absorbed by the premature infant. This therapy was instigated as a result of studies by Warkany (Warkany, J.: Congenital Malformations Induced by Maternal Nutritional Deficiency, J. Pediat. 25: 476-480 [Dec.] 1944) in which it was shown that a disease resembling retrolental fibroplasia in many respects could be produced in young rats born of mothers who were deficient in vitamin A.

cates something of the waste factor inherent in these figures. Food waste often is especially large in institutions and public eating places, but may also be considerable in households in upper income groups.

For other nutrients apparent margins of supply over need should be generous, for foods and nutrients are seldom distributed in accordance with need among the persons in a family or among the families of a nation. Large numbers of persons probably get less than optimal quantities of one or more nutrients. Others have diets providing much larger quantities of some nutrients than the allowances suggest. If these latter groups continue to enjoy their liberal diets and if all those who consume less than recommended quantities were brought up to those levels, nutrient averages for the country as a whole would be much higher than they were in 1945 and 1946.

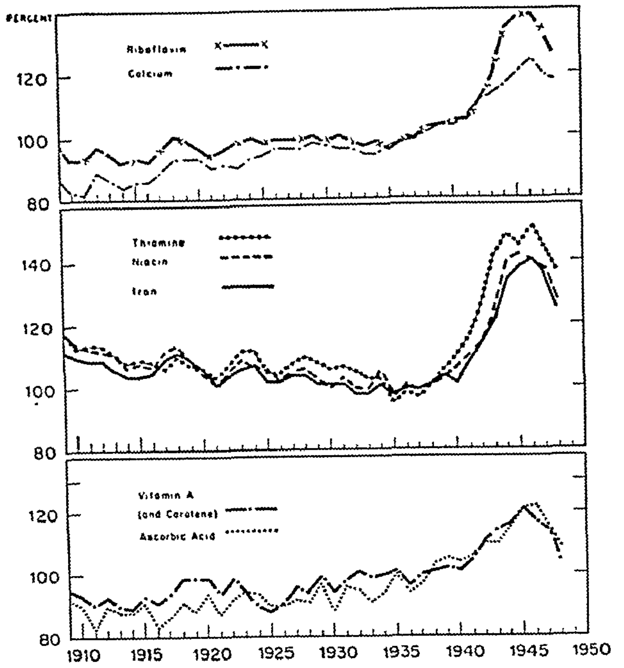

Chart 5.—Calcium, iron and vitamins in the United States per capita food supply, 1909-1948 (index numbers: 1935-1939 = 100). (Computed by the Bureau of Human Nutrition and Home Economics, United States Department of Agriculture.)

These facts should be kept in mind in any comparison of the nutrients in the per capita food supply with recommended dietary allowances. Other factors to be considered are those involved in any comparison of the calculated nutrient content of a diet with recommended allowances. For example, most tables of food composition suitable for use with foods "as purchased" make no allowance for losses that occur in home storage or in preparation for eating. For ascorbic acid and some of the B vitamins which are water soluble, heat labile and readily oxidized, these losses may be very high. On the other hand, recommended dietary allowances represent quantities to be ingested. They are considered high enough "to cover substantially all individual variations in the requirements of normal persons." However, much more needs to be known about variations in requirement, about the utilization of nutrients in the body and the possibility of synthesis of certain vitamins in the intestinal tract before a close evaluation of dietary adequacy can be made on the basis of dietary calculations and recommended allowances.

### INEQUITABLE DISTRIBUTION

Spot studies provide evidence that even in the peak years of supply, 1945-1946, many families did not have nutritionally good diets. In the summer of 1945 the Bureau of Human Nutrition and Home Economics obtained data regarding diets of families living in the open country in one county in Georgia and in one in Ohio. In the Georgia county, the food of one third of the white farm families and of two thirds of the Negro families provided less than two thirds of the dietary allowances recommended by the National Research Council, for one or more nutrients. The prevalence of such unsatisfactory diets was twice as high among sharecroppers and farm laborers as among owners and renters; it was somewhat higher among large than small families in the same income class.

Among Negro families in the Georgia county, vitamin A was the nutrient that most often seemed to be comparatively low in the diet. More than half of the families had food that provided less than two thirds of the recommended amounts. A greater consumption of green or yellow vegetables, of whole milk, butter or vitamin A fortified margarine would have increased the vitamin A value of diets. About a fourth of the families had food that furnished less than two thirds of the recommended levels of calcium and ascorbic acid, and the diets of nearly a fifth were correspondingly low in riboflavin. More milk and more vitamin C-rich fruits and vegetables would have improved the diets with respect to these nutrients also.

TABLE 1.—*Calculated Nutritive Value of U. S. Civilian per Capita Food Supply, Prewar, 1945 and 1948, Compared with Recommended Dietary Allowances (1948) of the National Research Council's Food and Nutrition Board*

| Nutrient | Nutritive Value per Capita per Day* | | | Per Capita Allowances Based on Recommendations of the National Research Council† |

* Computed by the Bureau of Human Nutrition and Home Economics on basis of estimates prepared by the Bureau of Agricultural Economics of apparent civilian consumption (retail basis) including foods supplied by farm and city gardens. No deductions have been made for waste of food in the home or for losses of nutrients in food preparation. No allowance has been made for nutrients added to the food supply through the use of baking powder, yeast, mold inhibitors, the added minerals in self-rising flour or for nutrients added in the processing of certain foods, such as vitamins used as antioxidants and calcium salts used in some canned foods.

† Recommended dietary allowances suggested for 17 sex-age-activity groups (National Research Council Reprint and Circular Series no. 129, Revised 1948) were weighted by the number of persons in each group according to 1948 population estimates.

‡ Vitamin A values expressed as international units, include carotene sources. Carotene was converted on the basis that 0.6 microgram of beta-carotene or 1.2 micrograms of other vitamin A-active carotenoids is equivalent to one I.U. of vitamin A. Current research suggests that many of the vitamin A values ascribed to carotene-rich foods in the literature need to be revised, and as they stand probably are too high to indicate physiologic utilization. Hence, the calculations in this table may considerably overestimate the margin above recommended allowances.

It is true in general that farm families are relatively well fed because they can and do raise so much of their own food supply. However, there are wide differences and its products other than butter averaged nearly 3 cups per day per person in 1945—as compared with less than 2 cups in 1909. As a result there was an increase of 40 per cent in the calcium content of the per capita food supply and a considerable increase in riboflavin.

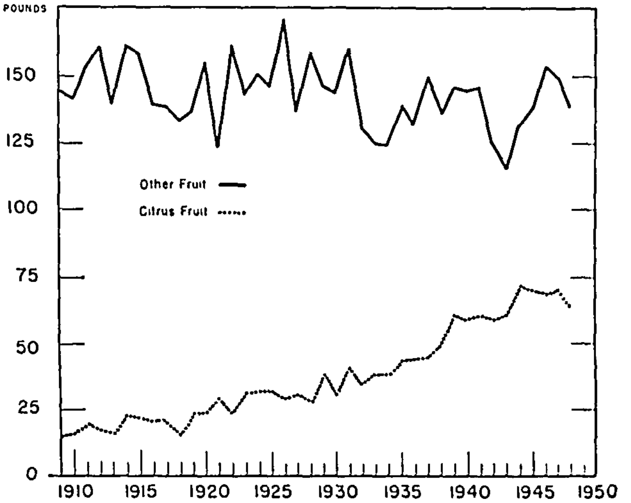

Chart 2.—Fruit: per capita consumption in the United States, 1909-1948. (Estimates of the Bureau of Agricultural Economics, United States Department of Agriculture.)

Consumption of citrus fruit (chart 2) and of leafy, green and yellow vegetables (chart 3) also has shown an upward trend during these years. More than four times as much citrus fruit was consumed in 1945 as in 1909. Yearly per capita consumption of meat, poultry and fish averaged 165 pounds (75 Kg.) or more (retail weight) in the period 1944 to 1947, compared with 137 pounds (62 Kg.) in the prewar years, 1935-1939 (chart 4).

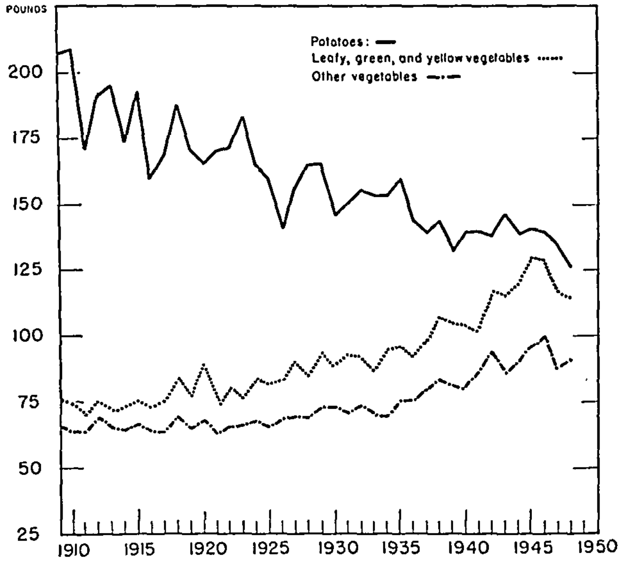

Chart 3.—Vegetables: per capita consumption in the United States, 1909-1948. (Estimates of the Bureau of Agricultural Economics, United States Department of Agriculture.)

While we have been eating more of some foods we have eaten less of others. Consumption of grain products and potatoes has declined considerably since 1909, although the downward trend was arrested during the war years, when supplies of fat and sugar were somewhat restricted.

The net effect of these shifts in consumption is shown in estimates of the nutritive value of the per capita food supply. Trends over a thirty-nine year period are shown in chart 5 in available supplies of calcium, iron and of five vitamins for which the National Research Council has suggested daily allowances. At the close of the war the calculated quantities of most nutrients were higher than at any time during the thirty-nine year period. For calcium the increase has been continuous. The similarity in the trends of calcium and riboflavin up to 1943 reflects the fact that milk is the most outstanding single food source of both; it has contributed from two thirds to three fourths of the calcium and nearly half the riboflavin in the national diet. After 1943 riboflavin increased more sharply than calcium because of its use in the enrichment of flour and bread.

For several nutrients the most striking increase has come since 1940. Higher levels of vitamin A (as carotene) as well as of ascorbic acid can be associated with the increased consumption of vegetables and fruits. The greatest increases were in thiamine, niacin, riboflavin and iron, which were higher by a third to a half than the prewar levels. About half of these increases were the result of the enrichment of flour and bread. The great similarity in the trend lines for these three nutrients is associated with their occurrence in foods. Two groups—grain products and meat, poultry and fish—furnish about half the iron and thiamine and about two thirds of the niacin in the per capita food supply.

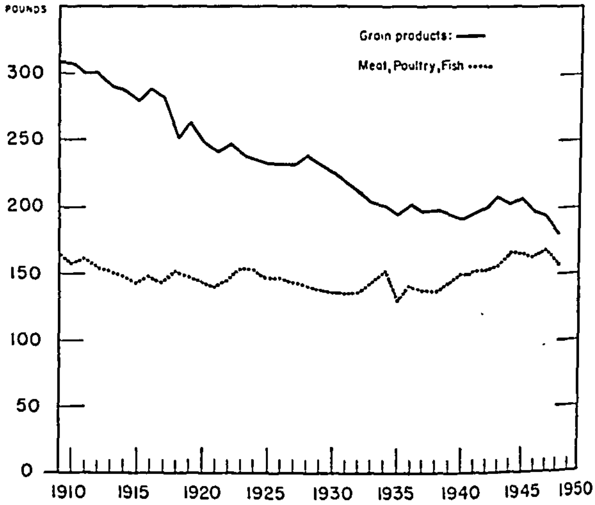

Chart 4.—Meat, poultry, fish; grain products: per capita consumption in the United States, 1909-1948. (Estimates of the Bureau of Agricultural Economics, United States Department of Agriculture.)

The peak years in average nutrient levels were 1945 and 1946, with 1948 somewhat lower. Compared with those of most countries of the world, these levels were exceedingly liberal, and they indicate a decided improvement over prewar levels in the United States, as shown in table 1. In 1935-1939 the national food supply did not furnish enough calcium to provide for every person in the country the quantities recommended by the National Research Council even if it could have been equitably distributed. Also, margins for the B vitamins were small compared with recommended amounts.

As they are now made, estimates of the nutrient content of the national food supply tend to be high. The large excess of calories over estimated needs indimeat, poultry, fats and eggs by families of different size living in Cumberland, Md.[3]

It is apparent that the larger the household size the smaller was the average expenditure per person for meat, poultry, eggs and fats. The average amounts spent in households of 2 persons would have been almost enough to purchase the quantities of these foods suggested in the moderate cost food plan of the Bureau of Human Nutrition and Home Economics. At October 1947 prices an expenditure of from $3.30 to $3.60 per person would have been needed to buy these quantities for a household of a moderately active man and woman. However, fewer than half the 2 person families in Cumberland were spending more than $3 per person; a third were spending less than $2, for which they scarcely could have purchased the quantities of these foods in the low cost food plan.

TABLE 4.—*Relation of Family Size to Diet (October 1947, Cumberland, Md.)*

| Household Size | Average Expenditure per Person per Week for Meat, Poultry, Eggs, Fats | Percentage of Families Whose Expenditures per Person for Meat, Poultry, Eggs and Fats Were in Excess of $2.00 | $2.50 | $3.00 |
|---|---|---|---|---|
| 2 or less | $3.20 | 64 | 55 | 46 |
| 3 | 2.59 | 70 | 35 | 25 |
| 4 | 2.38 | 53 | 42 | 28 |
| 5 | 1.84 | 38 | 17 | 17 |
| 6 | 1.59 | 11 | 11 | .. |
| 7 or more | 1.32 | 13 | 4 | .. |

In the 4 person household average expenditures per capita were close to the estimates of the cost ($2.50 to $2.70) of meat, poultry, eggs and fats in the moderate cost plan for 2 moderately active adults, a boy 13 to 15 and a child 7 to 9 years of age. Only 40 per cent of the 4 person Cumberland families were spending this amount or more.

In the 7 person households, average expenditures for meats, eggs and fats were only $1.32 per person per week. This is less than the amount needed in October 1947 ($1.45 to $1.60) to buy these foods in the low cost diet of the Bureau of Human Nutrition and Home Economics for a family of 2 adults, 2 teen-age and 3 younger children.

Differences between the low cost and the moderate cost food plans[4] are illustrated by the weekly quantities of foods suggested for the family of 4 previously described (table 5).

*Season.*—Few studies have been made to show seasonal differences in the nutritive content of family diets. There is evidence that considerable variation may be found, in part associated with seasonal availability of food supplies. For example, consumption of sweet potatoes in the South is highest in the months following their harvest and decreases in late winter as stored supplies diminish. This seasonal change in consumption influences the vitamin A value of diets. In towns and cities, abundant market supplies of fresh citrus fruit at reasonable prices may tend favorably to influence the ascorbic acid content of diets during late winter and spring.

Some seasonal variations may be the result of changes in the foods themselves. In general, vitamin values of foods tend to decrease during prolonged storage. Potatoes stored six months may have lost two thirds of the ascorbic acid present at harvest. Because they are eaten in fairly large quantities, potatoes constitute an important potential source of ascorbic acid. However, their contribution toward the end of their season may be much less than at the beginning. Farm families dependent for vitamin C on home-grown and stored potatoes, cabbage, apples and canned tomatoes and other vegetables may be running low in this nutrient along toward spring. Studies of ascorbic acid levels in plasma of school children in rural areas have shown this to be the case.

*Availability.*—It is usually taken for granted in the United States that if people have enough money they can buy the foods needed for a good diet. Yet this is not always true. In some sections of this country the local supply of milk has been inadequate for school feeding programs. Other examples could be cited to show how differences in availability of food supplies from one place to another may affect food consumption and the nutritional quality of the diet.

*Food Habits.*—Poor diets are often the result of poor food habits even when there is enough money for food. At almost any level of expenditure above a certain minimum, some families manage to have nutritionally good diets while others do not. For example, the figures below show the proportion of families with different kinds of diets obtained for about the same amount of money. These were village and city families in the North and West with food expenditures in 1936 between $2.77 and $3.45 per food expenditure unit per week. The proportions are as follows:

| | |
|---|---|
| Good diet | 24% |
| Fair diet | 64% |
| Poor diet | 12% |

Reports of poor food habits have been numerous in the last two or three years. Sometimes conclusions are based on the number of servings of different types of food in a day or a week as compared with some arbitrary meal pattern. In other studies conclusions relate to calculations of the nutritive value of the food consumed during a given period.

TABLE 5.—*Suggested Foods for Family of Four**

| | Low Cost Plan | Moderate Cost Plan |
|---|---|---|
| Leafy, green and yellow vegetables | 9 lb. 4 oz. | 13 lb. 4 oz. |
| Citrus fruit, tomatoes | 9 lb. 0 oz. | 11 lb. 0 oz. |
| Potatoes, sweet potatoes | 13 lb. 8 oz. | 11 lb. 0 oz. |
| Other vegetables, fruit | 7 lb. 8 oz. | 13 lb. 8 oz. |
| Milk (or its equivalent)† | 22 qt. | 23½ qt. |
| Meat, poultry, fish | 7 lb. 8 oz. | 10 lb. 8 oz. |
| Eggs | 20 (eggs) | 28 (eggs) |
| Dry beans and peas, nuts | 1 lb. 6 oz. | 12 oz. |
| Flour, cereals ‡ | 14 lb. 4 oz. | 12 lb. 4 oz. |
| Fats and oils § | 3 lb. 4 oz. | 3 lb. 10 oz. |
| Sugar, sirups, preserves | 3 lb. 4 oz. | 3 lb. 14 oz. |

* Two adults, a boy 13 to 15 years and a child 7 to 9 years.
† In cheese, cream, ice cream.
‡ Count 1½ pounds (680 Gm.) of bread or baked goods as 1 pound (454 Gm.) of flour.
§ Includes butter, bacon, salt pork.

A recent analysis of some 25,000 one day food records throws light on current food habits in four areas studied by the United States Public Health Service under their Nutritional Appraisal and Demonstration Program. These food records were obtained from persons, a large proportion of whom were children, being examined for physical evidence of nutritional deficiency. In one area in the suitability of individual farms for producing different kinds of food. Farm tenure makes a difference, also. Farm owners and renters are more likely to have extensive programs of food production for household use than are sharecroppers and tenants.

---

[3] Bureau of Human Nutrition and Home Economics: Unpublished ata.

[4] Based on September 1948 food plans. The following publications on d plans may be obtained from the Bureau of Human Nutrition and e Economics, United States Department of Agriculture: AIS-21, od for Two"; AIS-59, "Food for the Family with Young Children"; 71, "Food for the Family with School Children," and Miscellaneous n 662, "Helping Families Plan Food Budgets."

In the Ohio county, where income levels were somewhat higher and a greater proportion of the farm families were owners, family diets were somewhat better than in the Georgia county.

† Approximately the quantity of fluid milk to which the various dairy products (except butter) are equivalent in minerals and protein.

‡ Includes butter, bacon and salt pork.

§ Two thirds of the weight of baked goods has been added to that of flour, meals and cereals.

*Money for Food.*—Too little money for food is still a major cause of poor diets. In the Georgia county studied four fifths of the open country families had net money incomes of less than $1,000 in 1944-1945; in the Ohio county two fifths of the families had incomes under $1,000. Although in the country as a whole per capita incomes were more than twice as high in 1948 as in 1940, food prices also about doubled in that period. Food costs affect everyone, whereas not all families have shared equally in income advances. Consequently, large numbers cannot afford to buy the kinds and quantities of foods needed for good diets.

Food for 4 persons in quantities and types included in the city worker's family budget developed by the Bureau of Labor Statistics would have cost about $20 a week in June 1947 in the 34 cities in which the budget was priced. This budget represents a modest but fairly adequate standard of living. The kinds and quantities of food included are typical of those purchased by American families whose diets provide approximately the dietary allowances recommended by the Food and Nutrition Board of the National Research Council.

The trend in food prices is shown by the following figures. To follow a low cost food plan prepared by the Bureau of Human Nutrition and Home Economics, a family of 4 might have spent at average city prices:

| | |
|---|---|
| June 1936 | $ 9.00-$10.00 |
| June 1942 | 10.00- 11.00 |
| June 1945 | 13.00- 14.00 |
| June 1948 | 18.00- 20.00 |

In 1948 it would have taken about 50 per cent of a $2,000 family income to provide this diet and 35 per cent in 1945. Figures are not available to show how many 4 person families earned $2,000 or less in 1948. In 1945 it was estimated that about one fourth of the 4 person families in the United States had incomes under $2,000. Food costs for larger families are proportionately higher, of course. Of the total number of families of 5 or more persons, 30 per cent had incomes under $2,000 in 1945.

Even for small families food costs are frequently a problem. A fifth of the 2 person families had incomes under $1,000 in 1945. Expenditures for this low cost adequate diet would have amounted to $10 or $11 a week in June 1947, or about 55 per cent of the weekly share of an income of $1,000 for the year.

Even with the income increases that took place in 1947 and 1948, it is likely that thousands of families are spending a relatively large share of the family income for food at the expense of other needs and that unless they spend this money for food in a nutrition-wise fashion, and so handle and prepare the food as to conserve food values to the utmost, diets are deteriorating accordingly.

The relation of income to food consumption has been shown by many dietary studies. This relationship is most clearly shown by data from a fairly homogeneous sample—that is, from families of similar composition living in the same kind of community in the same region. Some of the most recent dietary studies were made during the war years when food rationing influenced normal consumption patterns and obscured somewhat the full effects of income. Hence the data selected to show the relation of income to diet in table 2 are from a nationwide study in 1935-1936; they show weekly consumption of selected foods by families of husband and wife, and 1 or 2 children under 16, living in villages of the New England, Middle Atlantic and North Central regions.

In successively higher income classes these families used larger quantities of milk, meat, fresh vegetables and fresh fruit. Consumption of eggs and fats increased slightly and that of grain products (in terms of flour equivalent) changed little, while quantities of dried peas and beans and of potatoes declined.

*Family Size.*—The kind of diet a family can have depends not only on family income but on the number of persons that income must support. Within a given income class, total expenditures for food increase with increasing family size, but food expenditures per person decrease. The figures in table 3 show food expenditures in September-October 1944 of city families with incomes for the year between $2,000 and $3,000[2]:

Table 3.—*Food Expenditures of City Families with Annual Incomes of $2,000 to $3,000 (September-October 1944)*

| Number of Persons in Family | Average Food Expense in 1 Week | |
|---|---|---|
| | Per Family | Per Person |
| 1 | $ 9.76 | $ 9.76 |
| 2 | 14.42 | 7.21 |
| 3 | 16.53 | 5.51 |
| 4 | 18.58 | 4.64 |
| 5 | 20.55 | 4.11 |
| 6 or more | 24.51 | 4.08 or less |

While there may be some economy in buying food in larger quantity, it is relatively small compared with the added cost of feeding more persons. The result is that diets of large families tend to contain smaller quantities of protective foods and, therefore, are less likely to be adequate nutritionally than diets of small families at the same income level.

Additional data on the relation of family size to the character of the diet are given below. These figures show the estimated expenditures in October 1947 for

---

[2] Wartime Food Purchases, Bulletin 838, United States Department of Labor, 1945.

Perhaps almost as important as the food itself is the educational experience provided by the school lunch. Eating well planned, well cooked meals day after day cannot fail to be influential in establishing good food habits. This experience will be most effective if accompanied with an integrated program of nutrition education throughout the curriculum.

The present federal school lunch program operates under the National School Lunch Act, which was passed in 1946. In the school year ending June 1948, nearly 45,000 schools participated in the indemnity plan, which means that sponsors were reimbursed by the government for part of the local purchases of food, provided that the meals served met certain specifications. In the peak months more than 6,000,000 children had a school lunch, with the peaks maintained longer than in 1947. Indications are that as the states work out better provisions for administering the program it will expand and go forward on a more stable and permanent basis.

In addition to the federal assistance given by reimbursement in the indemnity plan, the Department of Agriculture makes available for use in the lunch program special purchases of certain foods. These foods provide an important nutritional contribution to the meals served. Purchases for the year 1947-1948 included such foods as nonfat dry milk, cheese, dried eggs, dried fruits, peanut butter, sweet potatoes and concentrated orange juice.

The school lunch program provides one means for more equitable distribution of national food supplies in accordance with need. If expanded to include all children in school it would go far to safeguard the nutritional health of this group. Less attention has been given in the United States to meeting the special food needs of expectant and nursing mothers, infants and preschool children. In some countries these groups are given high priority in the distribution of available foods.

*Home-Produced Food.*—Food raised for family consumption not only spares cash for other needs but improves the family diet as well. The kinds of foods that are home produced on many farms—milk, eggs, meats, vegetables and fruit—are good sources of the nutrients likely to be low in diets of many families. Even the city backyard garden is worth while; families who raise their own vegetables tend to eat more. At the same time they are taking advantage of freshly harvested products, thereby avoiding the nutrient losses often incurred in usual marketing procedures. For many families more extensive or better planned home production offers the most feasible way of improving diets.

*Education.*—The importance of education as a factor in raising nutritional levels cannot be overemphasized. Every one needs to know how to select an adequate diet. The lower the income the more difficult it becomes and the more important it is that the food dollar be spent to best advantage. However, many persons who can afford good diets do not know enough about food selection.

Knowledge of nutritional requirements and how they may be met by foods, while far from complete, has advanced far enough to offer sound guidance in our teaching. But the application of the knowledge we have has lagged behind its development. Nutrition education in a broad sense includes convincing people that what they eat makes a difference. Experience has shown that motivation is the most difficult hurdle to surmount in trying to change food habits. It is essential that the physician, nurse, nutritionist, teacher and other key persons in the community have a strong personal conviction of the importance of the right food for the growth and development of children and for optimal health and well-being at all ages. For this they also need scientific information about food values in relation to cost, in order to understand the practical aspects of feeding problems. While an able job in nutrition education is being done on many fronts, more widespread and more adequate education in all aspects of the nutrition problem is needed by every one from health officers and other physicians down to the food manager for the family and the individual consumer. Determining the ultimate success in the broad practice of nutrition and holding the key to the adequacy of American diets is the housewife who spends the family food money, who prepares the family's three meals a day and who guides the food habits of children in their formative years. The physician as one of the influential members of society must give his support to this aspect of training for homemaking.

# Council on Pharmacy and Chemistry

## NEW AND NONOFFICIAL REMEDIES

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

Austin Smith, M.D., *Secretary.*

### ESTROGENIC SUBSTANCES (WATER INSOLUBLE) (See New and Nonofficial Remedies 1947, p. 343).

The following dosage forms have been accepted:

Cole Chemical Co., St. Louis 8

**Aqueous Suspension Estrogenic Substances:** 20,000 I. U. per cc., 10 cc. vials. Preserved with chlorobutanol 0.5 per cent.

**Solution Estrogenic Substances in Oil:** 2,000 and 5,000 I. U. per cc. in peanut oil, 1 cc. ampuls; 10,000 I. U. per cc. in peanut oil, 1 cc. ampuls and 10 cc. vials.

Reed & Carnrick, Jersey City, N. J.

**Aqueous Suspension Estrogenic Substances:** 20,000 I. U. per cc., 5 cc. and 10 cc. vials. Preserved with chlorobutanol 0.50 per cent.

Kremers-Urban Co., Milwaukee 12

**Aqueous Suspension Estrugenone with Benzyl Alcohol 2%:** 250,000 I. U. per cc., 5 cc. vials; 20,000 I. U. per cc., 1 cc. ampuls and 5 cc. vials.

U. S. Patent 377,549.

### PROTEIN HYDROLYSATE (See The Journal, March 6, 1948, p. 693).

The following additional dosage form has been accepted:

Interchemical Corporation, Biochemical Division, Union, N. J.

**Solution Elamine (modified casein hydrolysate) 10% with Dextrose 5%:** 600 cc. bottles. An acid hydrolysate of casein from which glutamic and aspartic acids have been partially removed and to which tryptophane has been added. It is virtually salt-free. No preservative is added.

U. S. Patent pending.

### FOLIC ACID (See The Journal, May 22, 1948, p. 367).

The following dosage form has been accepted:

Walker Vitamin Products, Inc., Mt. Vernon, N. Y.

**Tablets Folic Acid:** 5 mg. and 10 mg.

## DIAGNOSIS OF CANCER

A recent article in the *Scientific American* contains deprecatory remarks on the histologic diagnosis of tumors and other statements which are contrary to current medical opinion.[1] Supporting scientific data are not supplied. The lessening of confidence in the value of biopsy and microscopic study which may result from the article needs to be condemned. Microscopic examination for diagnosis of tumor is not infallible. The methods need to be constantly improved, and additional supplementary diagnostic methods should be sought. Nevertheless such examination is today still one of the most useful diagnostic procedures, and in many instances the most exact practical method of diagnosis.

The article under discussion deals with the heterotransplantation of tissue as a test for cancer. In performing this test small pieces of tissue are implanted into the anterior chamber of the eye of an alien species of animal—generally the guinea pig or rabbit. If the cells are cancerous they survive and grow; if they are normal, precancerous or from a benign tumor they fail to grow. In addition to cancerous tissue only normal embryonic tissue gives a positive reaction. The author advocates this biologic test—namely, successful heterologous transplantation—as a reliable test for cancer. He states, "A pathologist who examines tumor tissue under the microscope may observe significant details of form and structure, but he can never determine its malignancy from the appearance alone." This statement is contrary to the experience of physicians who know that cancer can usually be so recognized. Any pathologist who cannot diagnose tissue sections with a high degree of accuracy is unworthy of his specialty. His competence in this work is established by examination prior to certification by the American Board of Pathology. Greene does not offer evidence in support of his surprising statement, and a search of the literature does not reveal such data in his past publications.

The article further states, "Of two tumors with cells that look exactly alike, one may remain static or even disappear while the other inexorably spreads and kills the patient." If the author is here speaking of tumors which were diagnosed as benign by microscopic criteria, he is correct only with respect to the extremely rare examples of "benign metastasizing tumors"; he is wrong as far as the ordinary experience is concerned. If he is referring to tumors which are diagnosed as cancer on section, he is almost equally in error because spontaneous regression of such tumors is exceedingly rare. The well trained, experienced pathologist makes few mistakes in distinguishing tumors which will have a benign behavior from those which will run a malignant course, and such tumors rarely, if ever, "look exactly alike" to the experienced observer.

The article also attributes to the "biological view" a "fundamentally new concept of cancer," namely, that it ". . . is not the result of a sudden transformation, but is the final product of a developmental process." This concept is not new. It may be found in many old papers and books on tumors. A recent textbook[2] devotes much space to this idea. Many tumors may gradually or suddenly increase in degree of malignancy. Such tumors include, among others, mixed tumors of the salivary glands, neurofibroma, giant cell tumor of bone, laryngeal papilloma, pigmented nevus, bronchial adenoma and adenomatous polyp of the stomach and colon.

The statement is made that ". . . patients with disorders diagnosed as cancer by morphologist not infrequently make a complete recovery, whereas a diagnosis of cancer based on the behavior of the tissue is invariably followed, in spite of all attempts at treatment, by the death of the patient." Few, if any, patients on whom a diagnosis of cancer has been made by a competent pathologist make a complete recovery without treatment. Formerly, before such treatment was available, persons with tumors of similar morphology invariably died, as they still do today if they fail to have proper treatment. These results establish the cancerous nature of such tumors beyond question. Some forms of cancer which formerly had a mortality of about 100 per cent now show a high rate of cure (e. g., mammary cancer, carcinoma of the larynx, etc.). If the heterotransplantation technic is positive only in cases which are invariably fatal, then it is failing to detect many cancers. Perhaps the method is finding only the most highly malignant cases. The author concedes that there are different degrees of malignancy. To reject as malignant all tumors which fail to grow after heterotransplantation is unjustifiable on the basis of information now available.

---

[1] Greene, H. S. N.: On the Development of Cancer, Scient. Am. **179**: 40, (Dec.) 1948.

[2] Willis, R. A.: Pathology of Tumors, St. Louis, C. V. Mosby Co., 1948.

An example of superiority of microscopic examination over heterologous transplants in diagnosing cancer is well illustrated by the first case cited by the author: A tumor on two occasions failed to grow after inoculation into guinea pig eyes and takes as proof of malignancy by this technic were obtained only on the third attempt (with the second tumor recurrence). The microscopic diagnosis of fibrosarcoma, in contrast, was already made on the first surgical specimen. This diagnosis was correct, as was subsequently shown by rapid recurrences of the tumor after surgical removal on two occasions and eventually by the development of metastases.

The transplantation technic is slow and expensive, and it fails to distinguish between nonneoplastic lesions and benign tumors—information which is often desirable from the specimen. The justification for risking the lessening of public confidence in the established diagnostic method of microscopic examination is questioned.[3]

## ARE MEDICAL CARE PRICES EXCESSIVE?

Elsewhere in this issue is a comparison of the final 1948 Consumers' Price Index with the preliminary index of medical care prices of the United States Bureau of Labor Statistics. The entire cost of living index was 171.2 for 1948; the Bureau of Medical Economic Research of the American Medical Association estimates that the index of medical care prices, a small part of this cost of living index, will be only 141 for 1948. The base period 1935-1939 equals 100. This spread of 30 points compares with a spread of 27.6 points in 1947—159.2 and 131.6.

Again it appears certain that the prices charged by the physicians, dentists and hospitals for rooms have not risen as fast as the cost of living. These figures were developed by an agency of the federal government. These data clearly show that the cost of living in 1948 was much higher than the level of prices which the American people were paying for the various medical care items sampled by the field representatives of the United States Bureau of Labor Statistics.

The index for hospital room rates will probably be 212 for 1948 as compared with 179.6 in 1947. This high index of 212 is included in the general medical care index of 141; if it were not included, the latter would be much below 141. Actually the hospital is a buying and selling institution. Since it buys goods and services and sells them soon after purchase in the form of services to patients, the hospital cannot escape contemporary inflation.

These estimates should set at rest a good many wild and irresponsible statements about the exorbitantly high prices being paid for medical care. The statements are simply untrue if we are to be guided by the well known cost of living index of the United States Department of Labor. Physicians generally may not realize that this cost of living index is widely used in the United States as a basic formula for wage adjustment.

## A SECRETARY OF HEALTH, EDUCATION AND WELFARE

Recently the Committee on Expenditures of the House of Representatives held hearings on the creation of a cabinet post for health, education and welfare. First to appear was Mr. Oscar Ewing, who spoke in favor of such a cabinet position. Newspapers generally report that Mr. Ewing is himself a candidate for this cabinet office. The American Medical Association was represented at the hearings by Dr. John W. Green of California. Dr. Green emphasized the record of the American Medical Association since 1884, urging the creation of a separate department of health under a cabinet officer. Repeatedly representatives of the American Medical Association have petitioned Congress and various presidents of the United States urging such consolidation of health activities. Dr. Green pointed out that an examination of the various proposals to group health activities of the federal government under one head indicates that this may be accomplished in a number of ways. The most commonly considered conceptions are:

1. A separate Department of Health whose head has cabinet status.
2. Combining all health activities of the federal government in a separate agency not of cabinet status.
3. Combining health activities with other activities of the federal government in one department.

He then indicated still further the reasons why the medical profession feels that there should be a single Department of Health rather than an agency with three divisions:

> The American Medical Association is strengthened in its position that there should be a single Department of Health by the reports recently submitted by the Hoover Commission. It is apparent that one of the nation's greatest interests is in the health of its citizens, and health is of such a nature that, to be most effective, it must be individualized. The Association has recently issued a program emphasing the importance of this point of view.
>
> There is some difference of opinion as to whether the Secretary should have the qualifications of a practicing physician or whether his duties could not be discharged as well if he were not a medical practitioner. We cannot accept the statement which has been made that a physician competent to manage such a department or bureau cannot be found. To us it seems that the first function of such a department should be to guarantee the public that it will have available adequate medical care. This involves decision and perspective in the medical and public health fields which only a trained practicing physician can possess. Good administration is vital, and the Secretary should have as his aide an Under Secretary who is a thoroughly trained administrator.

---

# Current Comment

## OUR GREATEST CHILD HEALTH PROBLEM

A statistical summary[1] of some of the important causes of death at school age, 1945-1946, gives the lie to recent irresponsible statements concerning the health conditions of our children. A recent release from what should certainly be considered an unimpeachable source (National Office of Vital Statistics) again clearly shows that the greatest problem is continuously and increasingly one of accident prevention. "In a total of 32,960 deaths from all causes in 1946 among persons 5 to 19 years old, 12, 342 or 37 per cent of all deaths were caused by accidents as compared to 35 per cent in 1945 and 34 per cent in 1941, the last prewar year." Deaths from accidents among children 5 to 9 years of age were three times as numerous as the combined number of deaths from poliomyelitis and pneumonia, the greatest nonaccidental killers and perhaps the most feared of childhood diseases. In the 10 to 14 age group accidents outranked diseases of the heart, the single greatest nonaccidental cause of death, 3,153 to 656, or nearly 5 to 1. Even among young persons 15 to 19 years of age, when tuberculosis is the greatest cause of fatality with heart disease and pneumonia next in line, accidents accounted for nearly twice as many deaths as the three together. In an analysis of mortality figures A. D. Battey, senior statistician for the National Safety Council, summarizes in an accompanying article as follows:

> Among school children 5 to 14 years old, preventive medicine has proved its effective power. In 1930, 19 out of 100,000 of these children died of pneumonia and influenza; in 1946, only 5 out of 100,000 died of these diseases. In 1930, 12 out of 100,000 died of tuberculosis; in 1946, fewer than 4. In 1930, 13 out of 100,000 died of appendicitis, and 12 of heart disease; in 1946, only 2 out of 100,000 died of appendicitis and 5 of heart disease.
>
> In 1930, 36 out of 100,000 children 5 to 14 years old died of accidents; in 1946, 29, an improvement of only 19 per cent. This relatively small decrease indicates the need for more effective work in the field of accident prevention.

Our present major problems in reduction of mortality for these age levels are: (*a*) improved programs of accident prevention; (*b*) bettered public health programs and facilities for the prevention, diagnosis and treatment of tuberculosis; (*c*) research into the causes and control of the greatest killers such as heart disease, cancer and poliomyelitis, and (*d*) education of the public to early use of available facilities for care of these conditions. Obviously these programs of safety, public health, research and education must be widely implemented before further progress can be achieved through medical care. Significantly enough, the medical profession, through its national state and local associations and societies, for years has been doing everything possible to effectuate these programs. Here are established needs, well defined areas in preventive medicine in which government—national, state, and local—has broad responsibilities and in which complete cooperation by the medical profession is assured.

## SALT SUBSTITUTES—A WARNING

The American Medical Association and the Food and Drug Administration have issued warnings concerning the use of preparations that have been sold as salt substitutes. These warnings were based on reports of several deaths which, it is claimed, followed the use of preparations containing lithium chloride. Certain therapeutic measures require the restriction of sodium chloride in the diet, which patients who prefer food flavored with salt do not relish. To provide flavoring, some manufacturers have made available salt substitutes, at least several brands of which contained lithium chloride, which now is known to possess harmful possibilities. The products containing lithium that have been available are reported to include food-sal,® salti salt® and west-sal.® The early symptoms of lithium poisoning are similar to the symptoms of heart and kidney diseases which require a salt-free diet, and include drowsiness, weakness, loss of appetite, nausea, tremors and blurring of vision. It has been suggested that patients who have been using lithium-containing preparations for prolonged periods may be given solution of sodium chloride if their medical problems will permit the temporary use of this substance, but there is doubt in some centers that sodium chloride affects lithium excretion. An intensive program by the Food and Drug Administration and the manufacturers is now under way to recall all lithium-containing salt substitutes from the market. Details concerning the deaths and other untoward effects that have been reported will appear in early issues of The Journal. In the meantime, the Council on Pharmacy and Chemistry also is initiating an investigation to gain additional facts. No lithium-containing salt substitute is advertised in the publications of the American Medical Association.

## THE DAN GILBERT LETTER

Not long ago the National Physicians Committee circulated to the medical profession a letter by one Dan Gilbert, who was early in his career at the age of 26 years associated briefly in Washington with the notorious Gerald Winrod. Later Gilbert resigned from any connection with Winrod, and, when John Rogge was associated with the Department of Justice in Washington, Gilbert was chief witness against Winrod in a case brought by the government. The circulation of the letter by Gilbert to Protestant ministers and to the medical profession has been bitterly condemned by many hundreds of physicians who have written to the office of the American Medical Association in Chicago and who have in some places held protest meetings on the subject. The Journal of the American Medical Association authorizes the statement that the Gilbert letter was sent without the knowledge of any official of the American Medical Association, that every official of the American Medical Association joins in condemning the letter as an expression of medical opinion in this country and that the American Medical Association does not require allies of doubtful repute in its campaign for the maintenance of a high quality of medical care and for freedom in medicine in our country.

# ORGANIZATION SECTION

## THE PHYSICIAN'S FEDERAL INCOME TAX

Prepared by the Bureau of Legal Medicine and Legislation, American Medical Association

Federal income taxpayers on a calendar year basis must on or before March 15 do two things: (1) They must file their final returns for the year 1948 and (2) they must file a declaration of estimated tax for 1949.

### REVENUE ACT OF 1948

This act effected numerous changes in existing law that will in many instances result in a saving to taxpayers. One of the most important changes relates to the splitting of income, for tax purposes, between husband and wife and the filing of joint returns. If either the husband or wife has a surtax income in excess of $2,000, and if a joint return is filed, the family will realize a saving, since the splitting of the income will make applicable lower surtax rates.

A new exemption in the amount of $600 was created for taxpayers 65 years old or over. The ordinary personal exemption was increased from $500 to $600, as was also the exemption for the blind. A physician and his wife, both 65 years or older, who file a joint return may therefore claim four exemptions of $600 each and additional exemptions of like amount for dependents and in case either spouse is blind. The income tax returns have been much simplified during recent years and contain most of the basic information that a physician needs who prepares his own return or has it prepared by an office assistant, to complete the return. Additionally the Treasury Department last fall released a sixteen page booklet of instructions to aid taxpayers in completing Form 1040A, Short Form 1040 and Long Form 1040, one of which most physicians will find suitable to their needs. A copy of this booklet was forwarded to each prior taxpayer. Persons who will make returns or file estimates for the first time this year can undoubtedly obtain a copy of the booklet from the local office of the Collector of Internal Revenue.

Since this basic information has thus been made generally and readily available, it would serve no helpful purpose to repeat it here. The concluding portion of this statement, therefore, will discuss aspects of the law and its requirements that are of particular concern to physicians.

### GROSS INCOME

*Gross Income.*—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, assuming that the return is on a cash receipts and disbursements basis, plus such money as he has received from investments and from other sources.

If a physician receives a salary as compensation for services rendered and in addition thereto living quarters or meals, the value to the physician of the quarters and meals so furnished ordinarily constitutes income subject to tax. If, however, living quarters or meals are furnished for the convenience of the employer, the value thereof need not be computed and added to the compensation otherwise received by the physician. As a general rule, the test of "convenience of the employer" is satisfied if living quarters or meals are furnished to a physician who is required to accept such quarters and meals in order to perform properly his duties. For example, if a physician employed by a hospital is subject to immediate service at any time during the twenty-four hours of the day and therefore cannot obtain quarters or meals elsewhere without material interference with his duties and on that account is required by the hospital to accept the quarters or meals furnished by it, the value thereof need not be included in the gross income of the physician.

Tuition payments and subsistence allowances for veterans made under the G. I. Bill of Rights are not taxable income. Mustering out payments are likewise nontaxable.

### DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. As far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

*Office Rent.*—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

*Office Maintenance.*—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

*Supplies.*—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

*Equipment.*—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment, and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in each individual case.

*Dues.*—Dues paid to societies of a strictly professional nature are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are generally held to constitute personal expenses and as such are not deductible. If, however, membership in social organizations, such as a country club, is maintained both for personal and professional or business purposes and if evidence can be produced to substantiate the claim that a part of the expenses of such membership was incurred for business purposes, then it would seem that these latter expenses would be deductible. Further discussion of this particular aspect of the federal law will be found in a subsequent paragraph dealing with the deductibility of entertainment expenses.

*Postgraduate Study.*—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

*Traveling Expenses.*—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

*Entertainment Expenses.*—The deductibility of entertainment expenses, when incurred for business purposes, has been upheld, as applied to an actor, in the case of *Blakmer v. Commissioner,* 70 F. (2d) 255. In the case of *Jacobson,* 6 T.C. 1048, the taxpayer was allowed a deduction of expenses incurred for entertaining clients and employees of his law firm. The deductibility for such expenses by an attorney came before the U. S. Tax Court in the cases of *Clyde A. Armstrong* and *Ethlyn L. Armstrong v. Commissioner* and *Clyde A. Armstrong v. Commissioner,* which were decided on Aug. 29, 1947. In a memorandum opinion rendered by Judge Opper, this was said:

> Taxpayer, a Pittsburgh attorney, became a member of the University Club and the Duquesne Club in order to have available facilities for the entertainment of his clients; his purpose in joining the clubs was not particularly to make contacts productive of new business. In 1942, 1943 and 1944 the Commissioner disallowed deductions representing club dues, but allowed 50 per cent of the house bills incurred by taxpayer at each of the clubs during those years. The court finds that taxpayer used the club facilities not less than 50 per cent of the time for entertaining clients and other purposes incident to the practice of his profession, and allows the deduction of dues to that extent.

In the December 1948 issue of the *Medical Annals of the District of Columbia,* page 697, there was published correspondence that had passed between the Secretary of the Medical Society of the District of Columbia and the Internal Revenue Agent in the Baltimore Division, Treasury Department, in which the latter stated that if entertainment expenses incurred by a physician have a direct relation to the production of income, and can be supported by the taxpayer, they will be taken into consideration in determining his net taxable income.

*Automobiles.*—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeur's wages and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses; he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

## MISCELLANEOUS

*Contributions to Charitable Organizations.*—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. An individual taxpayer can deduct such contributions only to the extent that they do not exceed 15 per cent of his adjusted gross income. The physician may not deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

*Bad Debts.*—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

*Taxes.*—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible; but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income. Physicians may deduct state gasoline taxes and state sales taxes. In some states sales taxes are imposed on the seller, but if they are passed on to the buyer the latter may deduct them.

State income and use taxes are deductible; federal income taxes are not. Federal import, excise or stamp taxes are deductible only to the extent that they are attributable to business activities. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes, and not to raise revenue, the fee may not ordinarly be deducted as a tax. If such fees, however, are classifiable as a business expense they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business expense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

*Medical Expense.*—A taxpayer may deduct amounts expended for medical, dental and hospital expense for himself, his spouse or a dependent, not compensated for by insurance or otherwise, including amounts paid for health and accident insurance, according to a prescribed formula. The law limits the deduction to a maximum of (*a*) $1,250 if the taxpayer claims only one exemption; (*b*) $2,500 if the taxpayer is a single person or if married and filing a separate return and claims more than one exemption; (*c*) $2,500 if the taxpayers are married and file a joint return and claim two exemptions, $3,750 if three exemptions are claimed and $5,000 if four or more exemptions are claimed.

*Laboratory Expenses.*—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

*Losses by Fire or Other Causes.*—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

*Insurance Premiums.*—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

*Expense in Defending Malpractice Suits.*—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

*Sale of Spectacles.*—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold.

# Medical Economics

## MEDICAL CARE PRICES vs. COST OF LIVING

FRANK G. DICKINSON, Ph.D.
Director, Bureau of Medical Economic Research
Chicago

The final report of the United States Bureau of Labor Statistics places their Consumers' Price Index for 1948 at 171.2. The Bureau of Medical Economic Research has estimated that the index of medical care items, a small part of the total index, will stand at 141 for 1948. The base period 1935-1939 equals 100. If our preliminary estimates are later confirmed by the Bureau of Labor Statistics, 1948 will be another year in which the cost of living has been higher than the level of prices paid for medical care items. The final and official index of medical care items for 1948 will probably be 141 plus or minus 1.

The estimates for medical care items, a component part of the total index of prices paid by moderate income families in thirty-four large cities, are the means of the four quarterly indexes published by the United States Department of Labor. The cost of living index is used widely in the United States for the adjustment of wages although it is developed by a sampling process and covers only moderate income families in thirty-four large cities. In the accompanying table the final cost of living index and our estimates of the medical care indexes for 1948 are presented along with the final figures for 1947. No decimals are shown for our 1948 estimates, as these figures are preliminary. In 1947 the Consumers' Price Index was 159.2 and the medical care portion thereof was 131.6, a spread of 27.6. Apparently the spread in 1948 kept pace with the 1947 difference.

There are fifteen medical care items which are grouped into eight categories. Our estimate of the 1948 index for medical care excluding drugs is 145 or 4 points above the index of 141 for medical care including drugs. For drugs alone our estimate for 1948 is 122. In the five indexes under medical care excluding drugs, physicians' services (general practitioners only) is estimated at 136 for 1948. (Office visit at 138, house visit at 129 and obstetrical case at 154.) The 1948 index for surgeons and specialists combined is 136 (appendectomy at 133 and tonsillectomy at 139) and for dental care combined 146. The 1948 index for optical services combined is estimated at 124.

The most significant change is in the fifth category, hospital rates combined, which soared from 179.6 in 1947 to 212 in 1948. The index of 212 for hospitals is included in the index of 141 for all medical care and drugs combined; if it had not been included the latter would have been considerably below 141. Prices for laboratory and other services rendered by hospitals are not sampled; hence the hospital index covers primarily room rates. The hospital is uniquely exposed to the forces of inflation. It is a buying and selling institution with large current costs and few fixed charges. It buys goods and services and sells services soon after purchase. Its costs are not stabilized by such customary accounting items as depreciation and taxes because most hospitals are public institutions. Hence the changes in the current prices of food and fuel and in hourly wage rates are potent in changing hospital room rates charged to patients because there are no other costs of importance. The sharp increase in the index of hospital room rates for 1948 over 1947 reflects to some extent the failure of hospitals to raise their rates earlier. The recent decline in the prices of farm products has not yet materially reduced the operating costs of hospitals.

*Indexes of Component Medical Care Prices and the Consumers' Price Index, 1947, 1948*
*1935-1939 = 100 **

| | 1947 | 1948 |

| Physicians, combined (general practitioner, surgeon, specialist)....................... | 130.2 | 136 |

* The Consumers' Price Index for 1948 was obtained by letter from the United States Bureau of Labor Statistics; presumably this figure will be published in the February 1949 issue of the Monthly Labor Review of the United States Department of Labor. The indexes for medical care prices appeared in the following mimeographed publications of the United States Bureau of Labor Statistics: Indexes of Retail Prices of Services and Miscellaneous Goods, United States Bureau of Labor Statistics, LS 48-1093, March 1935 to June 1947, pp. 6-3, 7-3 and 8-2; Indexes of Retail Prices of Apparel, Housefurnishings, and Services and Miscellaneous Goods to Moderate Income Families in Large Cities of the United States, United States Bureau of Labor Statistics, LS 49-62, Supplement II issued August 1948, p. 3, and LS 49-1783, Supplement III issued November 1948, p. 4.

The accompanying table should be considered an extension of table 7 on page 14 of Bulletin 66, "The Cost and Quantity of Medical Care in the United States." A copy of this bulletin will be sent on written request to the Bureau of Medical Economic Research, American Medical Association, 535 North Dearborn Street, Chicago 10.

The Bureau of Medical Economic Research would like again to commend the physicians in the thirty-four large cities and their county medical societies for the time taken to provide field representatives of the United States Department of Labor with the requested information on fee schedules, the dentists who have provided their information, the hospitals and the oculists and the druggists. One cannot stress too strongly the value of this cooperation to the Bureau of Medical Economic Research. It needs this information for many research projects and hopes that physicians will continue to cooperate with the field representatives and statisticians of the United States Department of Labor.

# Official Notes

## ALUMNI AND FRATERNITY REGISTRATION AT A. M. A. CONVENTION

All medical school alumni organizations and medical fraternities which desire space at the Atlantic City Session of the American Medical Association for registration are requested to communicate with Dr. Walton Van Winkle Jr., American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois, and provide the following information: (1) name of organization; (2) name of person or persons who will be in charge of registration, and (3) if tickets are to be sold, (*a*) date and time of function, (*b*) location and (*c*) price.

The following regulations have been established regarding registration of alumni organizations and medical fraternities: 1. Only those organizations which have made application as outlined will be provided registration space. Space will be assigned on the basis of the order in which applications are received. 2. No sign, placard or other display larger than 24 inches by 24 inches will be permitted. 3. An organization must supply its own cash boxes, tickets, placards and one or more persons to handle ticket sales and registration. 4. Organizations will be permitted to register jointly but such arrangements must be made by agreement between the affected organizations and notice of such arrangements is to be sent to Dr. Van Winkle at American Medical Association headquarters. 5. The American Medical Association can assume no responsibility for tickets sold or money collected by alumni or fraternity organizations at the convention.

## RESOLUTION OF MILK PRODUCERS FEDERATION ON RURAL HEALTH

The National Cooperative Milk Producers Federation at their recent annual meeting in Portland, Ore., asked the following resolutions concerning the rural health program of the American Medical Association:

"General health and welfare of rural people can be well served by a constructive program of education and service such as that now being conducted by the American Medical Association through its *committee on rural medical service*. This program is making real progress. Through it the federation and other farm groups have been able to take part in offering counsel and advice toward extending an ever improving health program to more rural people."

# Medical Legislation

## STATE LEGISLATION

### California

**Bills Introduced.**—A. Constitutional Amendment 61 proposes the creation of a California **State Board of General Practitioners Examiners**, a certificate from which would authorize the holder to use drugs or what are known as medical preparations in or upon human beings and to sever tissue in the practice of minor surgery and to use any and all other methods in the treatment of diseases, injuries, deformities, or other physical or mental conditions, except major surgery. Major surgery is defined as the penetration by severing of the tissues of the body, the cranial, thoracic and abdominal cavities of the body and the severing from the body of any appendages. A. 955 proposes the creation within the department of professional and vocational standards of a board of registration for scientific medical research funds to register and to prescribe rules of conduct for persons desiring to engage in **the collection of funds for scientific medical research**. The Red Cross and the Community Chest would be exempt from the provisions of this proposal. A. 1010, to amend the Business and Professions Code, proposes that **any person** who is **licensed to practice medicine** and surgery in any other state, who is a graduate of a medical school approved by the Board of Medical Examiners, and who has applied for a physician's and surgeon's certificate in California, may be appointed to a medical staff of the Department of Corrections and may treat persons under the jurisdiction of that department for one year. At the end of that year, the applicant must have secured a physician's and surgeon's certificate in order to continue as a member of the staff. Until such person has secured his physician's and surgeon's certificate he shall not engage in the practice of medicine in the state except as provided in this proposal. A. 1072 proposes the enactment of **an alcoholics rehabilitation law** under the direction of the department of mental hygiene assisted by an advisory board, two members of which shall be physicians designated by the California Medical Association. A. 1074, to amend the law relating to **premarital tests**, proposes that the word "physician" as used in the premarital examination law shall include chiropractors. A. 1213 proposes the creation of a **Board of Physiotherapy Examiners** and defines physiotherapy as the performing for compensation of any professional service requiring special education, knowledge or skill by persons who undertake or represent themselves as able to treat or to alleviate ailment, deformity, fatigue, disease, injury, pain or any other physical condition by various modalities; electricity, electronics (except x-ray, radium), light, heat, water, corrective exercise and therapeutic massage. Nothing in this proposal would be construed to provide that the person representing himself as a physiotherapist is allowed to diagnose or to prescribe internal treatment. A. 1215, to amend the Business and Professions Code, proposes that all **prescriptions given to patients to be filled** by a pharmacist shall be in writing and shall be in legible, readily understandable, English. A. 1218, to amend the Business and Professions Code, proposes that **any person who practices** or attempts to practice any system or mode of treating the sick or afflicted or to alleviate ailments, deformity, fatigue, human disease, injury, obesity, pain or any other physical or mental condition by the use of massage, therapeutic massage, exercise or therapeutic exercise or by the use of the physical, chemical and other properties of electricity, heat, light or water, except by prescription or direction of a licensed practitioner, without having a license to practice medicine, osteopathy or chiropractic, shall be deemed guilty of a misdemeanor. A. 1219, to amend the Business and Professions Code, proposes that any person violating any of the provisions of the Business and Professions Code should be prosecuted by **the particular board which issued him his license.** A. 1270 proposes that **no blind person shall be denied** admission to any examination for a chiropractic license on the ground that he is blind. A. 1301, to amend the Business and Professions Code, proposes the creation of a State **Board of Examiners of Psychologists** and proposes that a person will be deemed to be practicing psychology who renders to individual clients or to the general public, for fees or personal profit, any professional service requiring the application of recognized principles, methods and procedures of the science and profession of psychology (such as the technics of psychometrics, psychotherapy, any form of individual analysis, and hypnosis and its applications) for the purpose of psychologic diagnosis, classification, evaluation, reeducation, guidance or personal adjustment. A. 1199, to amend the health and safety code, proposes the creation of an **Advisory Chronic Disease Council** to conduct a program directed toward the reduction of deaths and disability from cancer and other chronic diseases. A. 1501, to amend the Business and Professions Code, proposes to exempt from the provisions of the medical practice act the procurement of **blood specimens by venipuncture or skin puncture** for test purposes by a duly licensed laboratory technician or technologist on specific written authorization from a duly licensed physician and surgeon. A. 1602, to amend the civil code, proposes the creation **of a lien in favor of hospitals** on all causes of action for damages accruing to an injured person therein for the reasonable charges for hospital care, treatment and maintenance necessitated by the injuries giving rise to such causes of action. S. 431, to amend the Health and Safety Code, proposes the enactment of provisions relating to the regulation of the humane use of animals for diagnosis and treatment of human and animal diseases, for research in the advancement of veterinary, dental, medical and biologic sciences, animal and human nutrition, improvement and standardization of laboratory procedures and to provide for the issuance, suspension and revocation of licenses relating to **the use of animals for medical research** by the State Department of Public Health. S. 581 proposes to authorize the State Department of Public Health to assist in the development of community blood banks for the collection and distribution of **human whole blood and blood plasma.** S. 608, to amend the Business and Professions Code, proposes that any person licensed to practice medicine and surgery in any other state and who is a graduate of a medical school approved by the Board of Medical Examiners of California may be appointed to the medical staff of any state mental hospital or state home for the mentally deficient but **must not engage in the practice of medicine in the state except** so far as the inmates of the institution are concerned until he has secured a physician's and surgeon's certificate.

**Bill Enacted.**—S. 72 was approved Feb. 3, 1949. It permits the **Board of Osteopathic Examiners** to issue physician's and surgeon's certificates under certain circumstances.

### Georgia

**Bill Introduced.**—H. 600 proposes the creation of a Georgia **board of naturopathic examiners** and defines naturopathy as a health science to aid in the prevention, diagnosis and cure of human ailments, diseases and injuries. The proposal further states that the practice of naturopathy shall be construed to include the application, by means of any one or more of the psychologic, physical, mechanical, chemical or material forces or agencies of nature, and all according to the fundamental principles of anatomy, the sciences of psychology, mechanotherapy, articular manipulation, corrective and orthopedic gymnastics, neurotherapy, psychotherapy, hydrotherapy, suggestotherapy, electrotherapy, thermotherapy, phototherapy, chromotherapy, vibrotherapy, thalmotherapy, phytotherapy, biochemistry, external appliances, hygiene, first aid, sanitation, heliotherapy, mineral baths and dietetics, which dietetics shall include the use of vitamins and of foods of such biochemical tissue building products and cell salts as are found in the normal body, the use of vegetal oils and dehydrated and pulverized fruits, flowers, seeds, barks, herbs, roots and vegetables.

### Idaho

**Bill Introduced.**—H. 220 proposes the creation of a **board of naturopathy** and defines naturopathy as a system of manipulative, mechanical, mental and natural methods of treating the human body for the purpose of maintaining it in, or of restoring it to, a state of normal health. It includes the prescription and application or use of air, electricity, heat, light and water, and of earth and natural elements and fruits thereof.

## Kansas

**Bill Introduced.**—H. 115 proposes, among other things, that **an autopsy may** be performed upon the body of a deceased person by a physician or surgeon, when so authorized in writing by the decedent during his lifetime or by the decedent's surviving husband or wife, an adult child, a parent, or a brother or sister, and any physician or surgeon performing an autopsy so authorized shall not be liable on account thereof.

## Michigan

**Bill Introduced.**—S. 91 proposes that under certain circumstances **all children shall be immunized** against diphtheria, whooping cough, tetanus and smallpox before they register in any kindergarten or elementary school within the state unless they can show satisfactory evidence that they have been properly immunized and are adequately protected against said diseases.

## Montana

**Bill Introduced.**—H. 285 proposes to authorize autopsies or **postmortem examinations** on dead bodies in cases where dissection, autopsy or postmortem examination is directed or authorized by the last will and testament of the deceased and in cases where the husband, wife or next of kin charged by law with the duty of burial shall in writing authorize dissection, autopsy or postmortem examination for the purpose of ascertaining the cause of death. All dissections, autopsies or postmortem examinations involving dissection of any part of the human body shall be performed by a physician or surgeon duly licensed to practice such profession by the state board of medical examiners and on completion of any such dissection, autopsy or postmortem examination the physician or surgeon shall deliver a written report thereof together with his findings as to cause of death to the next of kin of the decedent or the representative of the decedent's estate or to other persons lawfully requesting such procedures.

## New Jersey

**Bill Introduced.**—A. 267, to amend the disability benefits law, proposes to permit a beneficiary under the act to receive care by a legally licensed **chiropodist** who, when requested by the commission, shall certify within the scope of his practice the disability of the claimant, the probable duration thereof and the medical facts within his knowledge.

## New York

**Bills Introduced.**—A. 786, to amend the vehicle and traffic law, proposes that applicants for a **chauffeur's license** shall present a certificate from a duly licensed physician attesting that such applicant has been examined and found physically competent to operate an omnibus. A. 1073 and S. 943, **to amend the public health law,** propose that no civil action shall be brought against a physician, officer or employee of the department of health in his personal capacity for alleged damages because of the manner in which professional services were performed, any act done or failure to perform any act while discharging his official duties, without leave of a judge of a supreme court first had and obtained. Such physician shall not be liable for damages in any action if he shall have acted in good faith with reasonable care and on probable cause. A. 1098 and S. 929 propose, among other things, to eliminate from the existing law relating to the **practice of physiotherapy** the requirement that licentiates may only administer drugs or practice medicine under the supervision of a duly licensed physician. A. 1097, to amend the workmen's compensation law, proposes to authorize employees to receive **treatment by podiatrist** licensed in the state. A. 1442, **to amend the insurance law** relating to nonprofit medical and dental indemnity and hospital service corporations, proposes that such corporations shall be open to participation of all duly licensed physicians and all duly licensed dentists without discrimination against the schools of medical and dental practice. S. 630 proposes to require every physician to report immediately to the health officer **every case of infantile paralysis** under his care. S. 911, relating to the refilling of **prescriptions for somnifacient drugs,** proposes that no prescription for a barbiturate or other hypnotic or somnifacient drug shall be refilled unless the prescription includes a statement by the prescriber that it may be refilled and specifying the minimum interval between fillings and the total number of refillings prescribed.

## Oklahoma

**Bills Introduced.**—H. 178 proposes regulations for the incorporation and licensing of charitable and benevolent nonprofit hospital service and idenmnity corporations and **nonprofit medical service and indemnity corporations.** H. 180 proposes to authorize physicians, chiropractors and osteopaths who were licensed to practice in the state of Oklahoma at the time the basic science act was passed in 1937, either on the basis of examination or reciprocity, and who are also licensed at the time this proposal is enacted to receive a certificate of ability from **the basic science board** without further examination. H. 182 proposes to authorize the various professional examining boards to make use **of the injunctive process** to restrain violations of the respective acts.

## Pennsylvania

**Bills Introduced.**—H. 190 proposes that **no state hospital** under the direction of the department of welfare having in attendance one or more physicians or interns shall increase its staff of physicians or interns unless authorized to do so by the Department of Welfare and no such permission will be granted as long as there is in the state any such hospital having one hundred beds or more but not having at least one licensed physician or intern. H. 220 proposes to authorize the department of health to investigate the **subject of alcoholism** in respect to rehabilitation and compile and maintain reliable statistics indicating the effectiveness of any rehabilitation programs carried forward by state-aided clinics for alcoholics, state hospitals and state-aided hospitals receiving alcoholics. H. 313 proposes the creation of a state **board of chiropractic examiners** and defines chiropractic as a philosophy, science and art of things natural, a system of locating misaligned or displaced vertebrae of the human spine, the procedure preparatory to and the adjustment by hand of such misaligned or displaced vertebrae and other articulations and tissues of the human body together with the use of scientific instruments of analysis. S. 223 proposes the establishment and erection within the limits of the city of Philadelphia of an institution to be known as the **Pennsylvania State Medical School.**

## Texas

**Bills Introduced.**—H. 69 proposes the creation of a **state board of naturopathic examiners** and defines naturopathy as that philosophy and system of the healing art embracing prevention, diagnosis and the cure and treatment of human ills, diseases, traumas, deformities, and functions by the use of the several properties of air, light, heat, cold, water, mechanics, electricity, manipulation and psychology, together with the use of such substances, largely nutritional, of plant, animal or mineral origin as are naturally found in and required by the body, excluding drugs and major surgery. Nothing in the proposal should be construed as authority to authorize a naturopathic physician to practice materia medica, major surgery or any other practice licensed by law. H. 95 proposes to provide for the competent training in health education of all prospective teachers and school administrators. S. 126 proposes the creation of a **Southwestern Medical College** of the University of Texas to be established in the city of Dallas. S. 149 proposes amendments to the food and drug act, among which would be the provision that **drugs sold at retail** and containing any quantity of amidopyrine, barbituric acid, pituitary, thyroid or their derivatives must conform with the labeling requirements of the act unless they are sold on a written prescription signed by a member of the medical, dental or veterinary profession who is licensed by law to administer such drug and the label bears the name and place of business of the seller, the serial number and date of the prescription and the name of such member of the medical, dental or veterinary profession. S. 171 proposes the creation of a Texas **board of chiropractic examiners** and defines chiropractic as the practicing or employing of objective or subjective means without the use of drugs or surgery for the purpose of ascertaining the alignment of the vertebrae of the human spine and the practice of adjusting the vertebrae by hand to correct any subluxation or misalignment thereof.

## Utah

**Bills Introduced.**—S. 169, to amend the marriage law, proposes that **applicants for a marriage license** shall file a certificate from any licensed practitioner of the healing arts which certificate shall state the age of the applicant, that the applicant has been given an examination for syphilis and that in the opinion of the physician the applicant is not *infected with syphilis or other venereal disease* in a communicable stage. S. 179 proposes to make permanent a board created to investigate *the* ***causes of alcoholism*** and to provide education thereon and treatment of alcoholics.

## Washington

**Bills Introduced.**—H. 13, **to amend the chiropractic act,** proposes, among other things, that any person who has complied with the provisions of the act may adjust by hand any articulation of the spine but shall not prescribe for or administer to any person any medicine or drugs now or hereafter included in materia medica nor practice obstetrics nor practice osteopathy or surgery. H. 77 proposes the creation of a Washington **State Naturopathic Association** to regulate the practice of naturopathy, which is defined as "the science and art of applied healing forces, emphasizing the application of prophylactic, diagnostic and therapeutic naturism; thus enabling the physician to prescribe or administer to human trauma or disease by applying any one or more of the psychological, physiological, mechanical, manual, chemical, biological or material forces or agencies in restorting a normal state of being." H. 135 proposes the creation of a **sanipractic physicians' examining board** of Washington and defines sanipractic as "the science and art of applied prophylactic and therapeutic sanitation, which enables the physician to direct, advise, prescribe or apply food, water, roots, herbs, light, heat, exercises (active and passive), manipulation, adjusting tissue, vital organs or anatomical structure by manual, mechanical or electrical instruments or appliances; or other natural agency, to assist nature restore a psychological and physiological interfunction for the purpose of maintaining a normal state of health in mind and body." H. 148 proposes that any hospital **shall be liable for damages** caused by the negligence of the hospital or any employee or agent of the hospital while acting within the scope of his employment. H. 157 proposes the creation of an **examining committee of physical therapists** and defines physical therapy as the treatment of any bodily or mental condition of any person by the use of the physical, chemical and other properties of heat, light, water, electricity, massage and therapeutic exercise which includes posture and rehabilitation procedures. The use of roentgen rays and radium for diagnostic and therapeutic purposes and the use of electricity for surgical purposes including cauterization are not authorized under the term. H. 167 proposes the creation in the Department of Health of a **division of cancer control** to make investigations concerning cancer, the incidence, the prevention and treatment thereof and the mortality therefrom, and to take such action as may be necessary to assist in a reduction in the mortality due thereto.

## West Virginia

***Bills Introduced.***—H. 16 proposes regulations for the compulsory immunization of school children for **smallpox and diphtheria.** H. 70 and S. 44 propose the establishment and maintenance in Charleston of a ***four year school of medicine*** and dentistry of West Virginia University. H. 144 proposes general amendments to the *medical practice act,* including the creation of a **medical licensing board,** the right to make use of the injunctive process in restraining violations of the act and the biennial registration of licentiates. S. 21 proposes to direct the state health commissioner to appoint a director of **the division of alcohol *studies and rehabilitation*** who shall have knowledge of the problems of alcoholism, treatment and rehabilitation of persons addicted to the excessive use of alcoholic beverages and for the promotion of preventive and educational programs in cooperation with state and local educational authorities.

*(From a Special Correspondent)*

Feb. 21, 1949.

### Detailed Report on A-Bomb Effects in Preparation

More than twenty military and civilian scientists are working on the first government-sponsored public report on the atomic bomb and its effects, according to an announcement by the Atomic Energy Commission. Civil defense indoctrination and training of armed forces personnel are two of the chief uses to which the book-sized report will be put. The volume is scheduled to be published in June.

The chapter on human damage from atomic explosion is being written by Dr. Shields Warren and Col. James P. Cooney. Both are members of the Commission's Washington staff, the former as director of the Division of Biology and Medicine and Colonel Cooney as a medical liaison officer. Assisting them is Dr. H. O. Whipple of the Los Alamos Scientific Laboratory's health division.

Another chapter will be devoted to civil defense problems that may arise from use of atomic weapons. Its author is Dr. George M. Lyon, of the Office of Civil Defense Planning and the Veterans Administration. Structural damage resulting from an air burst, basic physics of the bomb, radiologic effects in water and meteorologic problems are among other topics that will be covered in the yet untitled book.

The Atomic Energy Commission disclosed simultaneously that twenty-seven nations have now qualified to receive radioisotopes for medical and biologic research from the Oak Ridge "pile." Latest to comply with provisions are Mexico, Guatemala, Brazil, Colombia and Finland. Since September 1947, a total of 384 shipments have been made to nineteen nations. Isotopes of fourteen elements have been shipped, aggregating 7,193 millicuries.

### Atomic Energy Commission Reports on Progress in Medicine and Biology

Noteworthy advances in research in medicine and biology are cited in the fifth semiannual report of the Atomic Energy Commission submitted to Congress early in February. Radioisotopes produced by the commission are being used extensively in diagnosis and, to a lesser degree, in treatment of cancer, said the detailed report, adding that induction of cancer in experimental animals through application of radioisotopes has now become commonplace.

Relative to the Atomic Casualty Commission, financed with Atomic Energy Commission funds, the report discloses that laboratories are now functioning in Hiroshima and Kure, Japan, with 41 Americans and 140 Japanese engaged. "Thus far, the investigations have shown no evidence of any alteration in the offspring of exposed individuals, nor has there been any demonstrable increased incidence of stillbirths or miscarriages," according to the report. "In view of the fact that the gene injured by radiation is a recessive characteristic, it will be many years before a final statement can be developed on this problem."

### First Paraplegic Miners Hospitalized in Washington

Eight paralyzed coal miners, the first to be hospitalized in Washington under the United Mine Workers rehabilitation program, arrived in the Capital Friday, February 11, and were admitted to George Washington University Hospital. All were crippled in mining accidents. To date the United Mine Workers' Welfare and Retirement Fund has hospitalized two hundred such patients on the East and West coasts. Rehabilitation of the eight men in George Washington University Hospital will be supervised by Dr. Charles S. Wise.

### Psychiatrist and Dentist Added to Medical Advisory Board

Secretary of Defense Forrestal has announced the addition of Dr. Francis J. Braceland, of Rochester, Minn., and Dr. Daniel F. Lynch, of Washington, to the Armed Forces Medical Advisory Committee. The appointments bring the membership of the newly formed committee to eleven, exclusive of the lay chairman, Charles Proctor Cooper, and the Army, Navy and Air Force medical heads, who serve ex officio.

Dr. Braceland is professor of psychiatry at the University of Minnesota Graduate School and consultant to the Mayo Clinic. He also serves the Navy and Veterans Administration in consultant capacities. Dr. Lynch, a trustee of American Dental Association, is a dental surgeon in private practice here and is a consultant to the Navy Surgeon General, Army Medical Center and St. Elizabeths Hospital, Washington.

### Symposiums Planned by Research Study Sections

About one hundred educators, practitioners and others concerned with the various aspects of sanitation problems attended the first symposium of 1949 sponsored by the Division of Research Grants and Fellowships, National Institutes of Health. It was held January 26-27 in the Commerce Department auditorium, twenty-five scientific papers on recent research in milk and food sanitation being presented at the four sessions that were held. Presiding officers were V. M. Ehlers, Texas State Department of Health; Dr. W. L. Mallman, Michigan State College; Maj. Raymond J. Karpen, Army Surgeon General's Office, and Dr. F. C. Bishopp, U. S. Department of Agriculture.

Plans are being made for a symposium here in April sponsored by the antibiotics study section of the National Institutes of Health, and at least one or two others are expected to be scheduled for this spring.

---

# Coming Medical Meetings

Alabama, Medical Association of the State of, Montgomery, April 19-21. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Academy of General Practice, Cincinnati, Netherlands Plaza Hotel, March 7-9. Mr. Mac F. Cahal, 231 W. 47th St., Kansas City, Mo., Executive Secretary.

American Association for Thoracic Surgery, New Orleans, March 29-31. Dr. Brian Blades, George Washington University Hospital, Washington, D. C., Secretary.

American Association of Anatomists, Philadelphia, April 13-15. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Pathologists and Bacteriologists, Boston, April 15-16. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Broncho-Esophagological Association, Chicago, Drake Hotel, April 18-19. Dr. Edwin N. Broyles, 1100 N. Charles St., Baltimore 1, Secretary.

American College of Allergists, Chicago, April 14-17. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4, Secretary General.

American Orthopsychiatric Association, Chicago, Stevens Hotel, April 4-6. Nina Ridenour, Ph.D., 25 W. 54th St., New York 19, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Hotel Waldorf-Astoria, March 4 Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Physiological Society, Detroit, April 19-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary.

American Society for Pharmacology and Experimental Therapeutics, Detroit, April 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society of Biological Chemists, Detroit, April 17-22. Dr. Otto A. Bessey, 1853 W. Polk St., Chicago 12, Secretary.

American Surgical Association, St. Louis, April 20-22. Dr. Nathan Womack, University of Iowa, Iowa City, Secretary.

Arkansas Medical Society, Little Rock, April 14-16. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 1-4. Dr. H. Kenneth Scatliff, 30 N. Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 14-17. Miss Thelma Webb, 1133 Medical Arts Bldg., Dallas, Executive Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. Allan B. Phillips, 406 Sixth Ave., Des Moines 9, Secretary.

Michigan Postgraduate Clinical Institute, Detroit, Book-Cadillac Hotel, March 23-25. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Mich., Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

Ohio State Medical Association, Columbus, April 19-21. Mr. Charles S. Nelson, 19 E. State St., Columbus 15, Executive Secretary.

Southern Branch, American Public Health Association, Dallas, Texas, Baker Hotel, April 14-16. Dr. George A. Denison, 600 S. Twentieth St., Birmingham, Ala., Secretary.

Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.

Tennessee State Medical Association, Chattanooga, April 12-14. Dr. W. M. Hardy, 706 Church Street, Nashville 3, Secretary.

# GOVERNMENT SERVICES

## NAVY

### MEDICAL RESEARCH UNIT IN CAIRO

The United States Naval Medical Research Unit 3, established in Egypt in 1946, has undertaken two broad programs of medical research: 1. Study of human parasites responsible for causing or transmitting diseases of medical importance; at present these studies are in bilharzia and the biology of flies. 2. Study of the physiology and the biochemistry of patients suffering from such diseases as typhus, typhoid, amebiasis, relapsing fever and infectious hepatitis.

The Royal Egyptian Government last June leased to the United States Government an acre of land adjacent to the Abbassia Fever Hospital for twenty-five years, on which site the existing buildings are being remodeled and new ones being erected for laboratories in the fields of bacteriology, biochemistry, entomology, parasitology, physiology and virology and dental research.

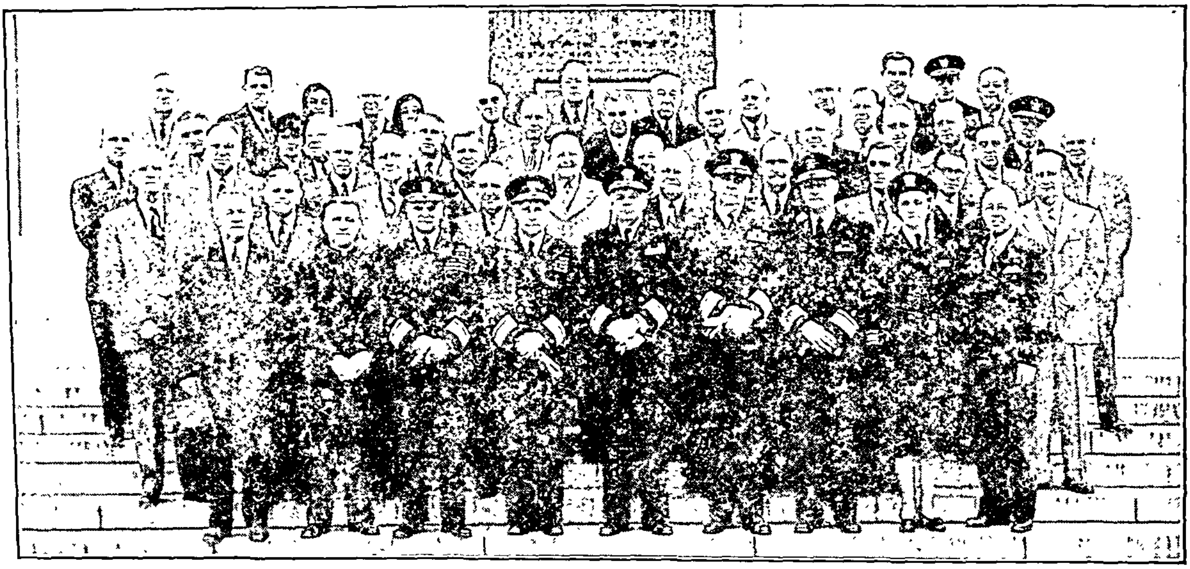
The laboratories will be staffed by American scientists and technicians, as well as by guest investigators from Egypt and other countries. The American honorary consultants will visit Cairo in a few months to meet with their Egyptian colleagues, of whom the following three were recently appointed: Sir Aly Tewfik Shousha Pasha, M.D., K.B.E., Com. O. Nil., Under Secretary of State for Medical Affairs; Hafez Afifi Pasha, M.D., G.O.O. Ismail, G.C.O.Nil., former Egyptian Ambassador to England, and Ibrahim Shawki Bey, M.D., Rector of the Fouad I University.

The American honorary consultants to Naval Research Unit 3 in Cairo are: Commander R. A. Phillips, Medical Officer in Command; Francis G. Blake, M.D., dean of the School of Medicine, Yale University, New Haven, Conn.; Lowell T. Coggeshall, M.D., dean of the Medical School, University of Chicago; Wallace O. Fenn, Ph.D., professor of physiology, School of Medicine, University of Rochester, New York, and John S. Lockwood, M.D., professor of experimental surgery, College of Physicians and Surgeons, Columbia University, New York.

### PERSONAL

Lieut. Emmett P. Bryant, M.R.C., of El Dorado, Ark., has been voluntarily recalled to active duty and will be assigned to instruction as a resident in obstetrics and gynecology at the Naval Hospital, Great Lakes, Ill.

### CONSULTANTS TO THE BUREAU OF MEDICINE AND SURGERY



The first joint meeting of honorary and reserve consultants was held at the Naval Medical Center, Bethesda, Md., Jan. 28-29, 1949:

First row, left to right: Frank H. Lahey, M.D., Hon. Consult., Boston; Paul A. McNally, S.J., Hon. Consult., Dean, Georgetown Medical School; Rear Admiral Joel T. Boone, M.C., U.S.N., General Medical Inspector; Rear Admiral Morton D. Willcutts, M.C., U.S.N., Medical Officer in Command, National Naval Medical Center; Rear Admiral Lamont Pugh, M.C., U.S.N., Deputy and Assistant Chief of the Bureau, who acted as chairman; Rear Admiral Arthur H. Dearing, Asistant Chief of Bureau for Personnel; Rear Admiral C. V. Rault, D.C., U.S.N., Assistant Chief of Bureau for Dentistry; Captain N. J. DeWitt, Superintendent, Navy Nurse Corps, and Meyer Weiner, M.D., Hon. Consult., Coronado, Calif.

Second row, left to right: Charles Sheard, Ph.D., Hon. Consult., Rochester, Minn.; A. C. Ivy, M.D., Reserve Consult., University of Illinois, Chicago; Edward A. Strecker, M.D., *Hon. Consult., Philadelphia; Roscoe Lloyd* Sensenich, M.D., Hon. Consult.; President, American Medical Association, South Bend, Ind.; Oswald S. Lowsley, M.D., Hon. Consult., New York; Clyde E. Minges, D.D.S., Hon. Consult.; President, American Dental Association, Rocky Mount, N. C.; W. Calhoun Stirling, M.D., Hon. Consult., Washington, D. C.; Lowell T. Coggeshall, M.D., Reserve Consult., Dean, Div. of Biol. Sciences, Univ. of Chicago, Chicago; Arthur M. Culler, M.D., Reserve Consult., St. Louis, and Wendell G. Scott, M.D., Reserve Consult., St. Louis.

Third row, left to right: Paul W. Greeley, M.D., Reserve Consult., Chicago; Howard K. Gray, M.D., Reserve [illegible] n.; Edward Leroy Bortz, M.D., Hon. Consult., Philadelphia; R. Louise McManus, Ph.D., Hon. Consult., New York; James [illegible] n. Consult., Atlanta, Ga.; Ernest Edward Irons, M.D., Hon. Consult., President-Elect, American Medical Association; Shiel [illegible] ve Consult., Boston; Joseph L. T. Appleton, D.D.S., Hon. Consult., Philadelphia; M. G. Westmoreland, M.D., Reserve Consu [illegible] College of American Pathologists, Chicago; F. J. Braceland, M.D., Reserve Consult., Rochester, Minn.; Philip E. Adams, [illegible] American Dental Association; Hon. Consult., Boston; Alphonse McMahon, M.D., Reserve Consult., St. Louis; Robert P. Fischelis, Pharm. D. Sc.D., Hon. Consult., Office of Secretary, American Pharmaceutical Association; Donald Hale, M.D., Reserve Consult., Cleveland; Daniel F. Lynch, D.D.S., Reserve Consult., Washington, D. C.; Sterling Bunnell, M.D., Hon. Consult., San Francisco; Joseph Barr, M.D., Reserve Consult., Boston; Capt. L. R. Newhouser, M.C., U.S.N., Bureau of Medicine and Surgery, and Paul Titus, M.D., Reserve Consult., Pittsburgh.

Last row, left to right: Edwin N. Broyles, M.D., Reserve Consult., Baltimore; Richard B. Cattell, M.D., Hon. Consult., Boston; Sister Mary Geraldine Kulleck, Hon. Consult., St. Louis; George M. Lyon, M.D., Reserve Consult., Washington, D. C.; Sister Mary Gregory Wurst, St. Louis; Marion Sulzberger, M.D., Reserve Consult., New York; Donald Anderson, M.D., Reserve Consult., Council on Medical Education and Hospitals, American Medical Association, Chicago; Edwin J. Cohn, M.D., Hon. Consult., Harvard Medical School, Boston; Ernest L. Stebbins, M.D., Hon. Consult., Johns Hopkins University, Baltimore; Donald G. Balfour, M.D., Hon. Consult., Rochester, Minn.; Gordon Barnes, Bureau of Medicine and Surgery; Comdr. Richard H. Fletcher, M.C., U.S.N., Bureau of Medicine and Surgery, and Winchell M. Craig, M.D., Reserve Consult., Rochester, Minn.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## CONNECTICUT

**Seminar on School Health Education.**—Yale University and twelve state and national health and education agencies will offer a graduate seminar in school health education June 27 to August 5. The program is designed to meet the needs of elementary and secondary school teachers responsible for instructing or organizing health education programs. Dr. Charles C. Wilson, professor of education and public health at Yale, is in charge of the course. Information may be obtained from Clyde M. Hill, chairman of the Yale University Department of Education, New Haven.

**Fellowship in Occupational Medicine.**—Yale University, New Haven, and the New Departure Division of the General Motors Corporation in Bristol announce the joint sponsorship of a one year clinical fellowship for a graduate course in occupational medicine to be directed by the Yale Institute of Occupational Medicine and Hygiene and the New Departure Division in cooperation with the state department of health. A short period of orientation in the Connecticut Bureau of Industrial Hygiene will be included in the section on industrial hygiene and safety. Candidates must be graduates of a class A medical school and rank in the upper two thirds of their classes. At least twelve months' rotating internship, or its equivalent in hospital training, is required along with an interest in occupational medicine and hygiene, public health, health conservation and case-finding programs. A license to practice medicine and surgery in Connecticut is also required. A candidate who completes his fellowship satisfactorily will be awarded a certificate. Information may be obtained from the Institute of Occupational Medicine and Hygiene at Yale University.

## ILLINOIS

**Public Health Association Meeting.**—The Illinois Public Health Association will hold its annual meeting at the La Salle Hotel, Chicago, April 7-8. Among the participants will be Drs. Leonard A. Scheele, Surgeon General, U. S. Public Health Service and Dr. Leroy E. Burney, state health director, Indianapolis. It is expected that the Illinois Association of Medical Health Officers will complete organization at the time of the public health association meeting. The decision to reactivate the health officers' association was made at the annual conference for the local and district health officers in Springfield last October. Dr. Winston H. Tucker, Evanston, is chairman of the committee.

**County Society Lectures.**—Lectures arranged through the Scientific Service Committee of the Illinois State Medical Society during March and April are as follows:

March 10, La Salle County Medical Society in Bloomington, Hermann W. Wellmerling, Bloomington, Fractures.
March 22, DeKalb County Medical Society in DeKalb, Roland R. Greene, Chicago, Gynecologic and Obstetric Endocrine Problems.
March 25, McDonough County Medical Society in Macomb, Ben W. Lichtenstein, Chicago, Multiple Sclerosis.
April 8, Kankakee County Medical Society in Kankakee, Charles L. Dunham, Chicago, Rheumatoid Arthritis with Particular Reference to the Differential Diagnosis of Rheumatoid Arthritis and Gout, Disseminated Lupus and Scleroderma.
April 19, Macon County Medical Society in Decatur, Henry Buxbaum, Chicago, Common Obstetrical Problems.
April 21, Logan County Medical Society, Richard Allyn, Springfield, Nephritis.
April 22, McDonough County Medical Society in Macomb, Paul A. Campbell, Chicago, Differential Diagnosis of Hearing Disorders.
April 28, Will-Grundy County Medical Society in Joliet, Philip Thorek, Chicago, Vagotomy for Peptic Ulcer and Ulcerative Colitis.

### Chicago

**Society News.**—The Chicago Dermatological Society on January 19 elected the following officers: Drs. Carl W. Laymon, Minneapolis, president, and James R. Webster, secretary-treasurer.

**Gift to Establish Eye Bank.**—A check for $50,000 has been received by Mercy Hospital for the establishment of an eye bank to be known as the Patrick A. Nash Memorial in the proposed $6,000,000 new Mercy Hospital on the Near North Side.

**Cleft Palate Institute.**—Northwestern University has established the Cleft Palate Institute under the cooperation of the schools of dentistry, medicine and speech. A grant of $25,000 from the Clara Abbott Fund of the university will provide partial support. The staff includes John R. Thompson, D.D.S., director and professor of orthodontia in the dental school, where the institute is situated; Dr. Frederick W. Merrifield, plastic surgeon; Harold Westlake, Ph.D., of the school of speech; Touro M. Graber, D.D.S.; Max Kuharich, D.D.S., and Gordon D. Howard, D.D.S., of the dental school, and Raymond Carhart, Ph.D., of the schools of medicine and speech. Patients are referred to the institute by social agencies, schools and doctors in private practice. In addition to giving diagnostic service and making recommendations for treatment, the institute will function as a research and teaching unit.

## INDIANA

**Postgraduate Course on Malignant Disease.**—The second annual postgraduate course on malignant disease is being offered to practicing physicians by the Indiana University School of Medicine, Bloomington-Indianapolis, on April 6-7 with the cooperation of the Indiana Cancer Society. Among the speakers will be Dr. Cornelius P. Rhoads, Memorial Hospital, New York.

**Research Wing for James Whitcomb Riley Hospital.**—Construction is under way on a $400,000 research wing at the James Whitcomb Riley Hospital for Children, Indianapolis, to provide laboratories and other space for research on diseases of children under the supervision of the Indiana University School of Medicine, Bloomington-Indianapolis. A $250,000 grant in support of this research program has been made by the Riley Memorial Association.

## KENTUCKY

**Personal.** — Dr. Tracy Jones, Harlan, has been appointed director of the Division of County Health Work, Kentucky State Department of Health, succeeding Dr. Richard B. Fulks, who resigned July 1. He will also act as deputy health commissioner.

**Dr. Phair Goes to Cincinnati.**—Dr. John J. Phair has resigned as director of the Louisville-Jefferson County Board of Health and head of the department of preventive medicine and public health at the University of Louisville School of Medicine to join the faculty of the University of Cincinnati College of Medicine, where he will also devote his time to study and research. Dr. Phair received his M.D. degree from the University of Cincinnati in 1929. He has been a member of the faculties of the University of Cincinnati and Johns Hopkins University, where he received his D.P.H. degree. Before and during the war he served as a medical consultant to the Secretary of War.

## LOUISIANA

**Personal.**—Dr. Charles E. Dunlap, professor of pathology in the Tulane University of Louisiana School of Medicine, New Orleans, has been appointed advisory editor of *Cancer Research*, official publication of the American Association for Cancer Research.

**Refresher Course in Pediatrics.**—The Louisiana State University School of Medicine, New Orleans, will present a refresher course in pediatrics at Charity Hospital and the medical school March 21-25. This program has been arranged primarily for the family physicians of Louisiana, and the attendance is restricted to 40. Dr. William L. Bradford, University of Rochester (N. Y.) School of Medicine and Dentistry, and Dr. Harry Gordon, University of Colorado School of Medicine, Denver, will assist the Louisiana State University faculty in presenting the program.

## MARYLAND

**Grant for Research by Dr. McCollum.**—The Robert Gould Research Foundation, Cincinnati, has made a grant-in-aid of $5,000 for research in 1949 by Elmer V. McCollum, Sc.D. professor emeritus of biochemistry at the Johns Hopkins University School of Hygiene and Public Health, Baltimore. The fund will enable Dr. McCollum to conduct research aimed at simplifying the method of the separation of amino acids from the products of digestion of proteins.

**New Health Television Service.**—On December 15 the first of a new series of weekly health television programs "Your Family Doctor," was given over Station WMAR-TV, Baltimore, under the joint auspices of the Baltimore City Health Department and the Medical and Chirurgical Faculty of Maryland. The programs will bring to the public up-to-date information concerning the individual and the community. They are broadcast each Tuesday evening at 8 o'clock on channel 2. The fictitious family doctor for the programs is Dr. John Worthington, a name selected because Dr. Worthington was the first health officer for Baltimore, appointed by the governor in 1792 when yellow fever was present in the community.

## MISSOURI

**Annual State Medical Meeting.**—The Missouri State Medical Association will hold its annual session in the Municipal Auditorium, Kansas City, March 28-30, under the presidency of Dr. Robert Mueller, St. Louis. Out-of-state physicians speaking on the scientific program are as follows:

Joseph T. Roberts, Little Rock, Ark., Pathology of Coronary Artery Disease.
Paul S. Barker, Ann Arbor, Mich., Electrocardiographic Changes in Coronary Disease.
Emmett B. Bay, Chicago, Acute Myocardial Infarction.
Wesley W. Spink, Minneapolis, Undulant Fever.
Winfred Overholser, Washington, D. C., Role of Psychiatry in General Medicine.
Howard R. Mahorner, New Orleans, Modern Surgical Procedures for Carcinoma of the Colon and Rectum
Francis M. Woods, Brookline, Mass., Problem of Lung Cancer.
Arthur R. Colwell, Evanston, Ill., Treatment of Diabetes Mellitus with Intermediate Insulin.
Andrew C. Ivy, Chicago, and J. Dewey Bisgard, Omaha, Medical and Surgical Standpoints, respectively, of Gastric Pain.

A symposium on trauma will be presented March 29 with Dr. George A. Aiken, Marshall, as moderator of a panel of four physicians from the state. The annual banquet will be held Monday at 7:30 p. m., when Dr. Ivy will speak on "The Dangers of State Medicine."

## NEW YORK

**Fellowships in Public Health.**—The New York State Department of Health is offering fellowships to train physicians to qualify for public health positions in the state. Each carries a stipend of $3,600 a year. Types of training offered include that for health officer, tuberculosis physician, clinical consultant and laboratory director. Information may be obtained by writing to Dr. Franklyn B. Amos, director, Office of Professional Training, New York State Health Department, Albany 1.

**Postgraduate Instruction.**—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged a lecture to be given at the Arnot-Ogden Memorial Hospital, Elmira, March 16 at 4 p. m. Dr. Stanley E. Bradley, New York, will speak on "Nephritis and Lower Nephron Nephrosis." The Jefferson County Medical Society, meeting March 10 at 8 p. m. in the Hotel Woodruff, Watertown, will hear Dr. Samuel Standard, New York, speak on "Blood and Blood Substitutes."

**Lectures on Radium Therapy.**—The Educational Committee of the Westchester Cancer Committee has arranged to present three lectures on radium therapy to county physicians at the White Plains Hospital. On February 28 Dr. John Kelly, New York, will discuss the use of radium in the gynecologic field, and Willet F. Whitmore, D.Sc., New York, will speak on the use of radium in the urologic field. On March 7 Dr. William S. MacComb, also of New York, will discuss the use of radium on cancer involving the head and the neck.

### New York City

**Clinical Research Meeting.**—The Committee on Medical Education of the New York Academy of Medicine is extending an invitation to all research workers in greater New York City and neighboring cities within a radius of 100 miles to submit papers on the results of original research in clinical medicine to be presented at a meeting for this purpose June 1. Presentations should be submitted in abstract in triplicate not to exceed 500 words in length to the secretary of the committee not later than April. A formal invitation to participate in the June program will then be extended by the committee to authors of the selected papers. Preference will be given to papers that have not been presented before a national or local society other than intramural. The address is 2 East 103rd Street, New York 29.

**Study of Teaching Needs in American University.**—Dr. Henry E. Meleney, professor of preventive medicine, New York University-Bellevue Medical Center, has been granted a six months' sabbatical leave to make a study of public health teaching needs at the American University of Beirut, Lebanon. Under a grant from the Commonwealth Fund, Dr. Meleney will prepare a report of teaching needs on the undergraduate and graduate level in the school of medicine. Largest overseas educational institution supported by American philanthropy, the University of Beirut has 2,500 students, representing forty nationalities, mostly from Saudi Arabia, Palestine, Syria, Lebanon and Iraq. Since its founding eighty years ago, it has pioneered in introducing the American type of medical education. Dr. Meleney, a graduate of Columbia University College of Physicians and Surgeons, 1915, was a member of the staff of the Peking (China) Union Medical College for seven years and was associate professor of preventive medicine at Vanderbilt University before coming to the New York University College of Medicine.

**Mount Sinai Hospital Expansion Projects.**—To meet demands for service and to intensify educational and research activities, the Mount Sinai Hospital of New York has embarked on a $7,000,000 expansion program that will add a ten story maternal pavilion and two research laboratories to its present seventeen building plant. The buildings will have a 160 foot frontage on Central Park and will occupy about two thirds of a city block. The city has added to this lot by deeding to the hospital 99th Street between Fifth and Madison Avenues. The 160 bed maternity building will include an Institute of Biogenetics for education and research. Among its features will be provisions for "rooming-in" of the infant and the mother and an entire floor for 40 premature babies, the latter to be financed partly by a grant from the federal government under the Hill-Burton Hospital Survey and Reconstruction Act. The general laboratory building, a seven story structure, will have a floor space of 50,000 square feet. The hospital's chemistry, physics and bacteriology departments will be moved to this building, and the present quarters will be renovated for the exclusive use of the pathology department. The Institute of Research, named for Dr. Albert A. Berg, hospital staff surgeon who donated funds for its construction, will be limited to specialized investigative work by a small group of researchers. Current expansion will give the hospital, which now services almost 20,000 persons a year, a capacity of 1,000 beds and a group of twenty buildings extending from 101st to 98th Street and from Fifth to Madison Avenue.

## PENNSYLVANIA

**Conference on Psychiatric Research.**—The Western State Psychiatric Institute in Pittsburgh will hold its fourth annual Coordinating Conference March 31-April 1 on the Progress and Implications in Psychiatric Research. Among those appearing on the program are Dr. Oskar Diethelm, New York; Dr. Harry C. Solomon, Boston; Dr. Francis H. Sleeper, Augusta, Maine; Dean Ruth P. Kuehn, Pittsburgh; Miss Ester Garrison, Washington, D. C.; Mrs. Mildred Buchwalder Beck, New York; Elliott Rodnick, Worcester, Mass.; Dr. Frederick Wyatt, Framingham, Mass.; Davenport Hooker, Ph.D., Pittsburgh, and Dr. Warren S. McCulloch, Chicago. The dinner speaker will be Dr. George S. Stevenson, New York, medical director of the National Committee for Mental Hygiene, Inc., and president-elect of the American Psychiatric Association. His subject will be "The Citizen and the Community in the Advancement of Mental Health." All professionally interested persons in Pennsylvania and vicinity are cordially invited to attend.

### Philadelphia

**Dr. Houssay to Lecture.**—The H. B. Shmookler Memorial Lecture of Mount Sinai Hospital will be delivered by Dr. Bernardo A. Houssay, Buenos Aires, Argentina, on "The Role of the Hypophysis in Carbohydrate Metabolism and Diabetes" March 7 at 8:30 p. m. in the Barclay Hotel Ballroom.

### Pittsburgh

**Audiology Clinic.**—The first audiology clinic in Pittsburgh has been installed this year in the Eye, Ear, Nose and Throat Hospital for the treatment of hearing and speech defects. Dr. Lee Doerfler, professor of audiology in Northwestern University, has been named managing director of the department. Serving as executive director is Dr. Kenneth M. Day, hospital staff member.

## TEXAS

**Dr. Wright Honored.**—Dr. Elva A. Wright, Houston, was honored at a special meeting in the auditorium of Baylor University College of Medicine, Houston, marking the presentation by Dr. Wright of a $5,000 fellowship fund to the Texas Medical Center. A portrait of Dr. Wright, pioneer in the treatment of tuberculosis in Harris County, was presented to the hospital. Dr. Richard H. Overholt, Boston, president of the American College of Chest Physicians, spoke on "Surgery's Place in the Treatment of Pulmonary Tuberculosis." The program was sponsored by the staff and board of directors of the hospital and the Harris County Medical Society.

**Dr. Burns Goes to Kansas City.**—Dr. Beryl I. Burns, administrator of hospitals at the University of Texas Medical Branch, Galveston, and professor of anatomy, has accepted appointment as director of municipal hospitals for Kansas City, Mo., effective in March. While associated with the University of Texas Dr. Burns organized the first broad residency training program to be established in the state. Under his administration over eighty residents and fellows were appointed for the hospital services annually. Dr. Jack R. Ewalt, professor of neuropsychiatry and director of the Galveston State Psychopathic

Hospital of the university, will succeed Dr. Burns. Dr. Ewalt is a graduate of the University of Colorado School of Medicine, Denver, and has been associated with the Medical Branch of the University of Texas since 1942.

## WEST VIRGINIA

**Conference of Officers of Component Societies.**—Presidents and secretaries of county and area medical societies from every section of West Virginia joined with the eighteen member council of the State Medical Association at a meeting in Charleston on January 9 in initiating a campaign designed to make 1949 a "health and higher education year." The occasion was the annual conference of officers of component societies, and discussion at the all day meeting was limited to public relations, administration and the legislative program, which has the unanimous approval of the council and the fact finding and planning, and legislative committees.

## GENERAL

**Meeting of Anesthesiologists.**—A joint meeting of the American Society of Anesthesiology and its southeastern section will be held April 7-9 at the Statler Hotel, Washington, D. C. The papers to be presented will include among others a proposed plan for postgraduate training in anesthesiology, spinal anesthesia, group practice and thiopental sodium and curare for suspension laryngoscopy. Dr. Lloyd H. Mousel, Washington, D. C.; Edward B. Tuohy, Washington, D. C.; Perry P. Volpitto, Augusta, Ga., and Donald H. Stubbs, Washington, D. C., will preside.

**Meeting of Pathologists.**—The Middle Eastern regional section of the College of American Pathologists will hold a joint meeting in conjunction with the Philadelphia Pathological Society and the Philadelphia County Medical Society March 10 at the county society building in Philadelphia. The program is as follows:

Milton Rapoport, Philadelphia, Present Status of Micro-Chemical Methods.
John E. Gregory, Philadelphia, Hypersensitivity.
John R. Neefe, Philadelphia, Laboratory Aspects of Hepatitis and Other Liver Diseases.
Nathan Chandler Foot, New York, Melanotic Tumors.
Armand J. Quick, Milwaukee, Laboratory as an Aid in the Diagnosis and Prognosis of the Hemorrhagic Disorders.
Edward D. DeLamater, Philadelphia, Chemistry of Staining Reactions in Common Use by Pathologists.

The guest speaker for the evening program is Dr. William Boyd, Toronto, Canada.

**Campaign to Speed Medical Research.**—Uniting in a simultaneous effort throughout the United States, ninety-nine national scientific and civic organizations will seek to speed medical research through a campaign during March under the direction of the National Society for Medical Research. The campaign, to be directed against research bans erected by the antivivisection cult, comes at a time when legislative battles on the vivisection question are raging in many states. It will seek to clarify the role of animal experimentation and biologic research. Organizations cooperating include the American Dental Association, American Diabetes Association, American Medical Association, American Public Health Association, American Red Cross, American Veterinary Medical Association, Association of American Medical Colleges, National Research Council, National Foundation for Infantile Paralysis, National Science Teachers Association and U. S. Junior Chamber of Commerce.

**Survey of Industrial Health Facilities.**—A two year cross sectional survey of industry's health facilities, conducted by Dr. Clarence O. Sappington, Chicago, has been issued by the Industrial Hygiene Foundation, located at Mellon Institute, Pittsburgh. The field study, embracing 277 plants in 33 states and covering an industrial population of 1,180,551 employees, is published as a bulletin entitled "Industrial Health Department Functions and Relationships." Physical examinations of workers are the general rule in industry today, the investigation shows, and in about half the plants surveyed the examinations are used to aid in successful job placement. About 54 per cent of the plants surveyed had industrial hygiene services in some form. The report suggests the following improvements to existing services: (1) more emphasis on having a physician in charge of the service in establishments employing less than 1,500 persons; (2) nurses should work directly under the supervision of a physician, especially in small plants where the physician is on a part time basis; (3) greater use of dispensaries in groups under 1,000; (4) greater improvement generally in the extent and nature of services rendered in plants having less than 1,000 employees; (5) greater improvement for minor surgery and minor illness in these small groups; (6) greater use of periodic examinations in all groups; (7) greater use of industrial hygiene facilities, particularly in plants employing less than 4,000 persons; (8) greater use of dental services in all plants; (9) more instruction in health and safety; (10) physicians should participate in accessory activities such as rehabilitation activities, maintenance of individual health records under medical control, labor relations, job analysis activities and case finding, and (11) the health service department of the corporation should in all instances have the final word on health problems and should be in active and cooperative relationship with top management.

The report brings up to date material contained in Bulletin 99 of the U. S. Public Health Service, written in 1919 and entitled "Medical and Surgical Care of Industrial Workers.' The survey is available at $2 per copy from the foundation.

## PUERTO RICO

**Institute of Forensic Medicine.**—The insular government has established the first Institute of Forensic Medicine in a new two story $26,000 annex building to the Municipal Hospital of San Juan, operating under the auspices of the School of Tropical Medicine. It has its own autopsy and crime detention laboratories. The legislature of Puerto Rico approved an appropriation of $25,000 for initial expenses and $45,000 for operating expenses up to June 30. The institute now serves the whole island.

**Public Health Association Meeting.**—The eighth annual meeting of the Puerto Rico Public Health Association was held February 9-12 at the School of Tropical Medicine in San Juan with Dr. Rafael Timothee presiding. Visiting physicians included Drs. Herman E. Hilleboe, commissioner of health, New York; John B. Hozier, U. S. Public Health Service, New Orleans; Edward G. McGavran, public health school, University of North Carolina, Chapel Hill; W. McKee German, University of Cincinnati College of Medicine; John S. Moorhead, commissioner of health, Virgin Islands, and Glenn S. Usher, Meridian, Miss., U. S. Public Health Service.

## FOREIGN

**Swiss Internists Meeting.**—The annual meeting of the Swiss Society of Internal Medicine will be held in conjunction with the Swiss societies of cardiology and hematology in Lugano May 6-8. Subjects under discussion will be anticoagulants in the prophylaxis and therapy of thrombosis, poliomyelitis and diabetes.

**German Congress on Internal Medicine.**—The Congress of the German Society of Internal Medicine will be held in Wiesbaden April 25-28 under the presidency of Professor Curt Oehme, Medizinische Universitäts-Poliklinik, Heidelberg. The subjects to be discussed include psychosomatic medicine, protein metabolism and protein therapy, chemotherapy of cancer, tuberculosis and endocarditis and circulatory problems. Application for attendance and for reading papers should be addressed to the president so that the necessary permits to travel in Germany can be furnished in sufficient time.

## CORRECTION

**Dr. Upham, Past President of the American Medical Association.**—In an Ohio news item in THE JOURNAL of February 5, page 391, entitled "Dr. Upham Made Emeritus Member of Board," it was erroneously stated that Dr. Upham's successor on the Ohio State Medical Board was a former president of the American Medical Association. The statement, which was misplaced, refers to Dr. Upham himself, who served the American Medical Association not only as president, but, also, for many years, as a member of the board of trustees and of the Judicial Council.

# Marriages

THOMAS C. CLIFFORD, Shipman, Va., to Mrs. Wynanda Bulkley Blake in North Salem, N. Y., September 11.

EDWARD M. KRUSEN JR., Drexel Hill, Pa., to Dr. Ursula M. Leden of Chicago, in Minneapolis, November 13.

WILLIAM STARK to Miss Vivenne R. Rose, both of Washington, D. C., in Baltimore, December 25.

JAMES MATTHEW ANDREW, Columbus, Ohio, to Miss Elaine Laura Flickinger of Akron, September 4.

ROBERT CRAIG SHELBURNE, Rocky Mount, Va., to Miss Louise Hesson at Sweet Briar, September 15.

LEROY LYON HOLT to Miss Anne Elizabeth Owen, both of Birmingham, Ala., September 11.

# Deaths

**George Herbert Ramsey,** Ann Arbor, Mich.; born in Olean, N. Y., in 1891; Columbia University College of Physicians and Surgeons, New York, 1917; later received the doctor of public health degree, Johns Hopkins University School of Hygiene and Public Health, Baltimore; served overseas during World War I; formerly deputy commissioner for the Michigan State Health Department; from 1926 to 1933 on the faculty of Johns Hopkins and later on the faculty of University of Michigan School of Public Health; in 1933 appointed director of the division of communicable diseases for the New York State Department of Health; during his affiliation with Johns Hopkins spent sixteen months with the West African Yellow Fever Commission under the auspices of the International Health Division of the Rockefeller Foundation; served as commissioner of health of Westchester County; member of the American Public Health Association, serving as chairman of the section on epidemiology; past president of the American Epidemiology Society; died in Saranac Lake, N. Y., November 30, aged 57, of tuberculosis and heart disease.

**Frank Edward Simpson** ⊕ Chicago; born in Saco, Maine, Sept. 7, 1868; Northwestern University Medical School, Chicago, 1896; interned at the Cook County Hospital; in 1910 went abroad to study in Vienna and Paris; formerly adjunct professor of dermatology at his alma mater; an Associate Fellow of the American Medical Association; a charter member and one of the early presidents of the American Radium Society; member of the American College of Radiology, Chicago Dermatological Society and the Chicago Roentgen Society; author of "Radium Therapy" and "Radium in Cancer and Other Diseases"; served as attending dermatologist to Cook County Hospital, Henrotin Hospital, Alexian Brothers Hospital, Chicago Policlinic Hospital and the Wesley Memorial Hospital, where he died December 13, aged 79, of cirrhosis of the liver and myasthenia gravis.

**Josiah Charles Trent** ⊕ Durham, N. C.; born in Okmulgee, Okla., Aug. 7, 1914; University of Pennsylvania School of Medicine, Philadelphia, 1938; assistant professor of surgery at Duke University School of Medicine; secretary-treasurer of the Durham-Orange County Medical Society; certified by the National Board of Medical Examiners; member of the American Trudeau Society and the American Association of the History of Medicine; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; in charge of thoracic surgery at Duke Hospital, where he died December 10, aged 34, of lymphosarcoma.

**Lee Campbell Adcock,** Fairfax, Va.; Jefferson Medical College of Philadelphia, 1903; served during World War I; for many years senior medical officer with the Civil Service Commission; died in the Arlington (Va.) Hospital December 3, aged 70, of rupture of the aorta.

**Elvira Dudley Dean Abell,** Madison, N. J.; Cornell University Medical College, New York, 1911; past president of the New Jersey Tuberculosis League; served on the staffs of Memorial and All Souls hospitals in Morristown and the Overlook Hospital in Summit; vice president of the board of managers of the North Jersey Training School for Girls at Totowa; first woman member of the board of directors of Shonghum Mountain Sanatorium in Morristown; died December 8, aged 63, of cerebral hemorrhage.

**George Gabriel Armstrong,** Portsmouth, Va.; University of the City of New York Medical Department, 1891; member of the American Psychiatric Association; for many years associated with the Connecticut State Hospital in Middletown; died in a local hospital November 22, aged 79.

**Conrad Stolzenbach Baker** ⊕ Willimantic, Conn.; Yale University School of Medicine, New Haven, 1934; specialist certified by the American Board of Anesthesiology, Inc.; certified by the National Board of Medical Examiners; served during World War II; died November 13, aged 39.

**Goodman Bare,** Anderson, S. C.; Emory University School of Medicine, Atlanta, 1920; member of the American Medical Association; served as county health officer; died October 1, aged 54, of coronary thrombosis.

**Daniel Clarke Brennan** ⊕ Akron, Ohio; Harvard Medical School, Boston, 1912; past president of the Summit County Medical Society; served on the staff of St. Thomas Hospital, where he died November 28, aged 64, of coronary occlusion and diabetes mellitus.

**Thaddeus Constantine Cooper** ⊕ Ogden, Iowa; Northwestern University Medical School, Chicago, 1912; died November 11, aged 69.

**Robert Henry Cowley,** Berea, Ky.; Western Reserve University Medical Department, Cleveland, 1901; specialist certified by the American Board of Otolaryngology; for many years affiliated with Berea College Hospital, where he died November 20, aged 77, of coronary heart disease.

**Albert Elmer Cross** ⊕ Worcester, Mass.; Boston University School of Medicine, 1900; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the New England Ophthalmological Society; formerly member of the school committee; served in an advisory capacity to the local draft board during World War I; member of the board of governors of the Hahnemann Hospital; died in Bennettsville, S. C., November 6, aged 76, of coronary occlusion.

**Charles James Dean,** Portland, Ore.; Chicago College of Medicine and Surgery, 1909; died in the Providence Hospital November 22, aged 64, of arteriosclerotic cardiovascular renal disease.

**Eugene G. Fendley,** Leslie, Ark. (licensed in Arkansas in 1903); member of the American Medical Association; died November 1, aged 66, of heart disease.

**Robert Leslie Ferguson** ⊕ Arkansas City, Kan.; Kansas City (Mo.) Medical College, 1903; died November 5, aged 74, of cirrhosis of the liver.

**George Ray French,** Andover, Ohio; Western Reserve University Medical Department, Cleveland, 1896; member of the American Medical Association; past president of the Geauga County Medical Society; died November 17, aged 75, of coronary thrombosis.

**Charles Albert George,** Springfield, Mo.; Washington University School of Medicine, St. Louis, 1903; member of the American Medical Association; formerly county coroner and city health commissioner; died in St. John's Hospital November 19, aged 67, of cerebral arteriosclerosis.

**George Benjamin Gilmore** ⊕ Colorado Springs, Colo.; Northwestern University Medical School, Chicago, 1903; formerly secretary-treasurer of the El Paso County Medical Society; formerly city health officer; affiliated with the Glockner-Penrose Hospital, St. Francis Hospital and Sanitarium and Memorial Hospital, where he died November 28, aged 67, of nephritis.

**Eustace Thomas Goff** ⊕ Parkersburg, W. Va.; University College of Medicine, Richmond, 1913; member of the American College of Chest Physicians; died November 22, aged 62, of heart disease.

**Julian De Voine Guyot,** Jefferson City, Mo.; Jefferson Medical College of Philadelphia, 1906; member of the American Medical Association; died November 3, aged 64, of pneumonia.

**Merit Donald Haag** ⊕ Toledo, Ohio; University of Michigan Medical School, Ann Arbor, 1918; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; affiliated with Lucas County and Toledo hospitals; died suddenly in Dunedin, Fla., January 6, aged 56, of cerebral hemorrhage and hypertension.

**William Scott Hartford,** Champaign, Ill.; Hering Medical College, Chicago, 1906; served during World Wars I and II; died in Glendale, Calif., November 6, aged 64.

**James Clarke Healy,** Boston; Tufts College Medical School, Boston, 1927; member of the American Medical Association; assistant professor of pharmacology at his alma mater; affiliated with the Boston City Hospital; died November 19, aged 46, of pulmonary tuberculosis.

**William H. Hendricks,** Tifton, Ga.; St. Louis College of Physicians and Surgeons, 1897; member of the American Medical Association; an officer during World War I; served as mayor of Tifton, and as senator and representative from Tift County; killed in a traffic accident November 15, aged 75.

**John Martin Hogan** ⊕ Oshkosh, Wis.; Rush Medical College, Chicago, 1902; formerly medical director of the Wisconsin National Life Insurance Company; on the staffs of Mercy, St. Mary's and Alexian Brothers' hospitals; one of the founders of the Oshkosh Clinic; died November 19, aged 72, of coronary disease.

**William Clyde Hogan** ⊕ Bradford, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1902; fellow of the American College of Surgeons; member of the Association of Military Surgeons of the United States; served during World War I; on the staff of Bradford Hospital, where he died November 20, aged 74, of cerebral thrombosis with paralysis.

**Albert Roy Hogg,** Lexington, Ga.; University of Georgia Medical Department, Augusta, 1905; died November 23, aged 67.

**Charles Edward Horner,** Williamsburg, Ky.; Eclectic Medical Institute, Cincinnati, 1907; died recently, aged 66.

**Lawson Udell Hurlburt,** Norwood, N. Y.; University of the City of New York Medical Department, New York, 1890; member of the American Medical Association; died November 17, aged 87, of arteriosclerotic heart disease.

**William Bernard Johnston,** Reno, Nev.; Johns Hopkins University School of Medicine, Baltimore, 1901; died November 19, aged 72, of coronary occlusion.

**Edward Winslow Jones** ⊕ Pasadena, Calif.; University of California Medical School, San Francisco, 1930; formerly an officer in the regular navy; died in November, aged 48.

**William Edward Kelly** ⊕ Middletown, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1904; specialist certified by the American Board of Pathology, Inc.; member of the American Psychiatric Association and the American Society of Clinical Pathologists; affiliated with the Goshen (N. Y.) Hospital and St. Francis Hospital in Port Jervis; for many years pathologist at the Middletown State Homeopathic Hospital, where he died November 24, aged 71, of cerebral hemorrhage.

**Samuel Markle Kirkwood,** Batavia, N. Y.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1892; died in Genesee Memorial Hospital November 23, aged 83, of cerebral hemorrhage.

**Inez Lapsley,** McAfee, Ky.; Laura Memorial Woman's Medical College, Cincinnati, 1901; fellow of the American College of Surgeons; served on the staff of Christ Hospital in Cincinnati; died November 19, aged 74, of heart disease.

**David Henry Lawrence Jr.** ⊕ Denver; University of Colorado School of Medicine, Denver, 1932; assistant professor of surgery at his alma mater; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; affiliated with Denver General, Colorado General, St. Luke's, Children's, Mercy and Presbyterian hospitals; died in November, aged 41.

**George Donald Livingston,** Detroit; Wayne University College of Medicine, Detroit, 1938; member of the American Medical Association; served during World War II; affiliated with Grace and St. Mary's hospitals; died November 14, aged 35, of coronary thrombosis.

**Irving Bigley Love** ⊕ Milwaukee; Marquette University School of Medicine, Milwaukee, 1923; school physician for the city health department for many years; on the staff of St. Mary's Hospital; died in St. Mary's Hospital, Madison, November 23, aged 52, of cerebral hemorrhage.

**William DeVoe Lyman** ⊕ Grand Rapids, Mich.; Grand Rapids Medical College, 1906; fellow of the American College of Surgeons; served during World War I; affiliated with St. Mary's and Blodgett Memorial hospitals; died November 21, aged 72, of cerebral hemorrhage.

**Franklin Pierce Lynch,** New York; University of the City of New York Medical Department, 1891; for many years a medical missionary in the Belgian Congo; died in the Roosevelt Hospital November 20, aged 89.

**Howard N. Lyon,** Chicago; the Hahnemann Medical College and Hospital, Chicago, 1888; died in Morris November 29, aged 81, of cerebral arteriosclerosis and arteriosclerotic heart disease.

**James McGehee McAnally** ⊕ Reidsville, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1927; past president of the Rockingham County Medical Society and the Eighth District Medical Society; on the staff of the Memorial Hospital; surgeon for the Southern Railway; died in Baptist Hospital, Winston-Salem, N. C., recently, aged 46, of coronary thrombosis.

**Wheeler Scott McCall,** St. Louis; Barnes Medical College, St. Louis, 1910; served during World Wars I and II; died in the Veterans Administration Hospital, Jefferson Barracks, Mo., November 20, aged 61, of hypertension and myocardial infarction.

**Fenton Elmer MacCallum,** Pulaski, N. Y.; Baltimore Medical College, 1900; health officer of the town of Richland; member of the American Medical Association; died October 28, aged 72, of coronary thrombosis.

**Luther Love McDougal Sr.,** Booneville, Miss.; University of Louisville (Ky.) Medical Department, 1907; member of the American Medical Association; past president of the Northeast Mississippi Thirteen County Medical Society; formerly secretary of the Prentiss County Medical Society; for many years member of the state board of health; formerly superintendent of the Mississippi State Hospital, Whitfield; died in the North East Mississippi Hospital, November 19, aged 70.

**Robert Louis McGee** ⊕ Raleigh, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1932; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; affiliated with Rex Hospital, where he died November 11, aged 41, of polioencephalomyelitis.

**Charles A. J. McKenna,** Scarsdale, N. Y.; Fordham University School of Medicine, New York, 1921; served during World War I; medical examiner for the New York State Department of Labor; formerly affiliated with the Manhattan Eye, Ear and Throat Hospital and Misericordia Hospital in New York; died November 23, aged 52.

**Mack Laughlin McKinnon** ⊕ Lauderdale, Miss.; University of Tennessee Medical Department, Nashville, 1910; died in Rush Memorial Hospital, Meridian, November 20, aged 63, of a skull fracture received in an automobile accident.

**Harry Gray McNamee Jr.,** Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1937; member of the American Medical Association; formerly on the faculty of his alma mater; served during World War II; died in Kennedy Hospital, November 7, aged 36, of glioblastoma.

**Alexander McRobbie,** Swampscott, Mass.; University of Aberdeen Faculty of Medicine, Scotland, 1904; died November 21, aged 73, of coronary occlusion.

**John Henry Miller Madden,** Columbia, S. C.; Johns Hopkins University School of Medicine, Baltimore, 1939; member of the American Medical Association; secretary treasurer of the Second District Medical Society; served overseas during World War II; affiliated with Columbia Hospital, Providence Hospital and the Baptist Hospital, where he died November 21, aged 35.

**Frederick Fletcher Malony,** Dundee, N. Y.; Yale University School of Medicine, New Haven, 1901; member of the American Medical Association; served as county coroner; affiliated with the Soldiers and Sailors Memorial Hospital in Penn Yan and the Geneva (N. Y.) Hospital; died November 29, aged 73.

**Joseph Mandelberg,** Brooklyn; Cornell University Medical College, New York, 1919; served with the Veterans Administration; died November 12, aged 55, of coronary thrombosis.

**George Francis Mangone** ⊕ Union City, N. J.; University and Bellevue Hospital Medical College, New York, 1925; health officer; affiliated with the French Hospital in New York and Christ Hospital in Jersey City, where he died November 20, aged 47, of congestive heart failure and coronary sclerosis.

**Otis W. Martin** ⊕ Ralston, Neb.; University of Nebraska College of Medicine, Omaha, 1917; for many years associated with the Union Pacific Railway; served during World War I; died November 7, aged 57, of carcinoma of the kidney with metastases.

**Stonewall Jackson Martin,** Bowling Green, Ky.; University of Louisville (Ky.) Medical Department, 1904; died November 14, aged 82, of pneumonia.

**Samuel Abbot Volpert** ⊕ Lake Placid, N. Y.; Syracuse University College of Medicine, 1922; past president of the Essex County Medical Society; on the staff of General Hospital in Saranac Lake and Lake Placid General Hospital; died November 27, aged 49, of coronary thrombosis.

**Justin Miner Waugh** ⊕ Cleveland; Columbia University College of Physicians and Surgeons, New York, 1898; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served overseas during World War I; affiliated with the Cleveland Clinic; died in Cleveland Clinic Hospital November 24, aged 76, of cerebral hemorrhage.

**Samuel Weinberg** ⊕ Baltimore; College of Physicians and Surgeons, Baltimore, 1901; died November 26, aged 68, of coronary thrombosis.

**Edison Kerl Westhafer,** New Castle, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1905; member of the American Medical Association; served during World War I; formerly associated with the U. S. Public Health Service; died in Henry County Hospital November 9, aged 70, of coronary occlusion.

### The Working of the National Health Service

In the House of Commons a discussion has taken place on the working of the National Health Service, which was criticized by the opposition and defended by the Government. Sir H. Morris-Jones, a national liberal member, said that a large number of doctors were unhappy about many of the workings of this act; that in large industrial areas they had, on the whole, gained somewhat in remuneration; that in all other areas their incomes had gone down so seriously as to affect the morale and working power of the practitioner; that the whole basis of remuneration should be reconsidered; that there was much to be said for payment for each attendance, with a certain ceiling, whereby the state could make a grant-in-aid; that the basic salary was working very badly, and that the distribution of doctors was infinitely worse than ever. A conservative member asked whether the medical profession was not much overworked, with the consequence that it had insufficient time to give to serious illness. Were the people who really needed them getting the hospital beds?

For the Government Mr. L. J. Edwards, Parliamentary Secretary, Ministry of Health, said that there was no longer any doubt that the Health Service had been welcomed and used by all classes to an extent beyond expectation! In the family practitioner service some 40,000,000 have placed their names on doctors' lists. That is between 95 and 98 per cent of the total population. A 3 per cent margin of error was allowed for. Out of a total of about 21,000 general practitioners 18,165 have come into the scheme. They have written 75,000,000 prescriptions for medicines or appliances since the service began. Out of about 10,000 dentists in general practice 8,988 are now in the scheme. They have treated 2,200,000 patients, and a further 1,200,000 are under treatment at present. It looks as though the initial peak demand for dental services has passed, but the demand is still running at the rate of 130,000 patients a week. Over 2,500,000 persons have had their sight tested, and over 3,000,000 pairs of glasses have been supplied or are on order. It should be borne in mind that all these figures refer to a period of about six months during which the service has existed.

On the question of payments to doctors the Minister said that up to March 31 next they were estimated at $130,000,000, in addition to which there were contributions from the Government for superannuation amounting to $6,400,000. It was agreed with the profession that the mileage payments to rural doctors for 1947 should be increased to $5,200,000, but it is clear that this would not be sufficient to meet their needs, and the Government has agreed to provide a further $2,000,000 a year.

### Annual Meeting of the Association of Surgeons

The annual meeting of the Association of Surgeons of Great Britain and Ireland will be held in Dublin on May 26-28. The discussions arranged are as follows: "Surgical Ritual," to be opened by Sir Hugh Cairns, Sir R. Watson-Jones, Mr. Julian Taylor, Mr. F. Gill and Mr. D. M. Douglas; "The Use and Abuse of Streptomycin," by speakers to be announced later; "The End Results and Treatment of Injuries of Peripheral Nerves," to be opened by Mr. H. J. Seddon; other speakers to be announced later. Fellows and associate fellows are invited to submit the titles and precis of short papers to the honorary secretary by the end of January. Those requiring accommodation in Dublin should apply as soon as possible to Hewett's Travel Agency, Hewett's Corner, D'Olier St., Dublin.

### Freedom of Britain from Epidemic Influenza

This country has been singularly free from epidemic influenza in recent years. In the first quarter of 1948 the deaths from influenza in the great towns reached the lowest figure ever recorded. So far there is no indication this year of any epidemic of influenza in England. But Italy, France and Belgium have been suffering from epidemics of mild type, probably due to the influenza B virus. Two persons arrived in London from Paris on January 5 and showed symptoms suggestive of influenza. It is likely that during the past fortnight there have been numerous similar importations, but there is nothing to suggest that the disease is already spreading. While dissemination of the virus is almost inevitable, the outbreak need not necessarily reach epidemic proportions. The Ministry of Health has issued in the press "the golden rule" that anyone who has a headache, pains in the limbs and fever should go to bed in a room by himself and remain there under medical care until he recovers. Though it is free from influenza in epidemic form, scattered cases continue to occur from time to time throughout the country.

### New Health Records

The vital statistics for 1948 show three new health records. As the National Health Service did not come into force until the middle of the year, credit cannot be claimed for this, as it probably would if the service covered the whole year. The deaths registered in England and Wales during 1948 numbered 470,282, the lowest for eighteen years, in spite of an increase of population amounting to 3,500,000. This represents a record low death rate of 10.8 per thousand of population. There were 266,635 deaths of children under one year of age, giving a rate of 34 per thousand related to live births. This is the first time that the annual rate has fallen below 40, the previous lowest being 41. Stillbirths numbered 18,415, giving a rate of 23.1 per thousand live and stillbirths. This is also the lowest rate ever recorded. The number of live births was 777.648, a reduction of 109,172 from the peak of 886,820 in 1947 but substantially above prewar levels. The rise in the birth rate during and immediately after the war has been pointed out in previous letters to The Journal. It was explained as largely due to the marriage allowances paid to soldiers' wives. This is confirmed by the great fall in the birth rate which followed in the years of peace.

### Health Districts for Medical Training and Research at Batavia

Dr. J. W. Tesch, who was assistant of Prof. Dr. J. E. Dinger, director of the Queen Wilhelmina Institute for Hygiene and Bacteriology of the Faculty of Medicine, Batavia, published a fascinating report on "The Hygiene Study Ward Center at Batavia" (Thesis University of Leyde, 1948).

The plan for this study ward was conceived by the late Prof. E. Walch. This outstanding hygienist, himself a pupil of the School of Hygiene at Baltimore, was guided in this plan by the experience in the United States, where, in the neighborhood of various schools of hygiene, a quarter of the town is allocated as a study ward for the students. After his tragic death his idea has materialized under his successor, Professor Dinger, with the aid of the Public Health Service, the Queen Wilhelmina Jubilee Foundation and the Rockefeller Foundation.

The Study Ward was established in the Tanah Tinggi ward of the Senen subdistrict of Weltevreden, a section of Batavia with a population of 25,000.

The staff under the physician in charge consists chiefly of a midwife, a nurse for infants and preschool children, 4 home visitors (investigators) and an instructor of the visitors. The midwife does not attend confinements but collects all possible data regarding pregnancy, confinement and lying-in. She visits the pregnant women, traced by the investigator in their homes and urges them to avail themselves if necessary of expert assistance, which is then given by a midwife of one of the obstetric institutions operating in the ward.

The investigators make regular rounds, each in his own territory, collecting information regarding pregnancy and the hygienic and demographic conditions; keeping a look out for cases of sickness, for pregnant women and for infants found not to have birth certificates, and distributing bottles for the collection of fecal matter and sputum and making blood smears for malaria tests.

The instructor of the investigators calls on the families in which there are cases of sickness and arranges the further epidemiologic research work under the supervision of the physician in charge. The nurse for children makes a house to house call on all the newborn babies and makes propaganda for visits to the hygiene center. In the program of activities one finds as the most important subjects: the census of the population, vital statistics, environmental conditions, individual hygiene and preventive medicine, diet investigations and the epidemiology of typhoid, different forms of dysentery, worm infestations, tuberculosis, diphtheria, malaria, yaws, leprosy, measles, leptospirosis and filariasis.

During four years of work done in the study ward, a new census has been organized comprising a classification of the population according to occupation, economic status, etc., and a new apparatus for the registration of births. The environmental conditions were carefully studied and much attention was given to personal hygiene which, according to the author, will have a prominent place in the future of public health.

Regarding the epidemiology of typhoid, bacillary dysentery and diphtheria, rates were obtained of the frequency of bacillus carriers, contact and immune persons. The supposition that there must be many slight and unrecognized cases of typhoid among the population of the native districts of Batavia is not confirmed by this research, although in the surface water a heavy contamination with fecal bacteria and typhoid bacteria was found. This gives rise to another supposition, namely, that the contact with this surface water, besides spreading real cases, produces subclinical immunizing infections, which lead to an active immunity against typhoid.

Bacillary dysentery again showed itself to be one of the most important tropical diseases; relatively many carriers were found among persons chosen at random and among persons who had come in contact with dysentery patients. The results of the postmortem examinations are surprising indeed, as in 14 per cent of persons who had died of all kinds of diseases dysentery bacilli were traced. The morbidity and the mortality of bacillary dysentery among the group up to 4 years of age appeared to be thirty to forty times as great as among the older children and the adults.

The author obtained the general impression that in tropical surroundings a more rapid immunization against diphtheria takes place. The native school children of the study ward in the age group 5 to 6 years already showed a high incidence of Schick-negative reactions.

It may be expected that the investigations and survey described by Dr. Tesch are to be continued as soon as conditions will permit. The work in the study ward is of high educational and didactic value. At the same time it opens a rich field of epidemiologic research and stimulates the authorities who are responsible for the sanitary conditions in the district.

### Thrombophlebitis

At the annual meeting of the Sociedad Española de Cardiología, Nov. 27, 1948, at the Asociación de Médicos de Madrid, Dr. Fernando Martorell of Barcelona read an excellent article on "Phlebothrombosis and Thrombophlebitis of the Limbs." This article was based on careful observation by the speaker of 971 cases. Two hundred and twenty-two were in the acute phase, whereas 750 were seen in the phase of the sequels. From the etiologic point of view, puerperal thrombophlebitis is the most frequent. Primary thrombophlebitis is second in frequency. Pulmonary embolism occurred in 140 patients. It ushered in the clinical symptoms of thrombophlebitis in 70 cases and appeared after the clinical symptoms of thrombophlebitis in 66 cases. In the group of patients with sequels, 222 had edema, 172 induration and 341 ulcers. The speaker reviewed Oschner's and Bakey's theories on phlebothrombosis and thrombophlebitis. The differentiation is useful with respect to certain aspects of the disease, but it is advisable to retain the name thrombophlebitis in its generic sense, to prevent possible confusion. In the therapeutic field, it is obvious that immobilization of the thrombophlebitic limb is harmful, whereas in some cases administration of spasmolytic drugs and anesthesia of the sympatheticus are of value. Concerning the value of anticoagulants, the speaker emphasized that heparin gives good results whereas dicumarol® is dangerous and of less efficacy than heparin. However, dicumarol® should be resorted to in patients in whom heparinization is impossible and in those who had heparinization with a consequent favorable course of the disease and in whom prolongation of the anticoagulant effect is indicated. Operation is indicated only on thrombosed varicose veins, on thrombosis causing embolism and on septic thrombophlebitis. Active mobilization of the limbs is indicated as the best prophylactic measure. In the course of the sequels the postphlebitic ulcer is a frequent and painful complication. Lumbar ganglionectomy followed by extensive removal of the ulcer and application, with suture, of a free graft constitutes the recommended treatment. The graft is obtained with Padget's dermatome. Drs. C. Jiménez Díaz, of Madrid, the president of the Sociedad Española de Cardiología; Rodriguez Arias, of Barcelona, and A. Buylla, Varela and F. Vega Diaz, all from Madrid, took part in the discussion of Dr. Mortorell's article.

### Appoint Professor of Histology

Dr. J. L. Arteta was recently appointed professor of histology and pathologic anatomy of the Faculty of Medicine of Santiago de Compostela. His appointment was made by unanimous vote of all the members of the faculty. Dr. Arteta belongs to the school of Cajal. He was a pupil of Dr. J. F. Tello. He has held the following positions: assistant professor of histology and pathologic anatomy of the Faculty of Medicine of Madrid from 1940 to 1944; head of department of autopsies of the Hospital General of the Department of Pathologic Anatomy, of which Dr. M. Perez Lista is the director, and, most recently, professor of pathologic anatomy of the Escuela Nacional de Tisiología. Dr. Arteta is a permanent collaborator of the Instituto de Patología Médica, of which Professor Dr. G. Marañón is the director. He has published several articles in collaboration with Dr. Marañón. His articles on the nervous system are important, especially on the following subjects: changes of microglias on different experimental conditions; pathologic anatomy of the pellagrous tongue, and new technics of impregnation of the nervous system. He developed a rapid technic of biopsy, which is a modification of Terry's technic.

## DIABETES

*To the Editor:* An unfortunate error appeared in THE JOURNAL of January 1 which tended to reflect on the validity of my reported observations on vascular damage in diabetes mellitus. Dr. Elliott P. Joslin in his article, "Furtherance of Treatment of Diabetes Mellitus" (page 1) cited my study of 200 patients but inadvertently referred to the number as 20!

In critically evaluating these observations, Dr. Joslin unfortunately used as his source an abstract of a preliminary report rather than the more detailed paper which appeared in THE JOURNAL on Aug. 16, 1947. With respect to the manner in which the data were obtained, a point which seems to have disturbed Dr. Joslin, readers of THE JOURNAL will recall that "the patients were selected from the Metabolism Clinic of the Mount Sinai Hospital and private practice on the basis of detailed medical records dating from the onset of diabetes, with emphasis on regular ophthalmoscopic examinations, determinations of blood pressure and complete urinalyses."

A distinguished member of Dr. Joslin's own clinic, Dr. Priscilla White, makes an observation almost identical with mine, noting that "vascular disease occurred in 93 per cent of 220 juveniles surviving twenty or more years of diabetes." This is not materially different from my report of 100 per cent vascular damage in twenty-five years.

In fact, Dr. Joslin himself states in his JOURNAL article of January 1 that "more than 60 per cent of my diabetic patients die between the fifth and twentieth year of their diabetes." It seems to me that he and his associate, Dr. White, have proved my case.

No one regrets the existence of a pessimistic outlook on diabetes more than I, but no useful purpose can be served by denying the evidence which has been demonstrated. On Oct. 5, 1947 at the Seminar on Degenerative Lesions of Metabolism sponsored by the National Institute of Health, the chairman, Dr. Joseph H. Barach, opened the session by stating "So far, almost everyone who has discussed this topic seems to have corroborated Dolger's observations and faced the grim facts. Out of this, there will finally come a revaluation of our knowledge on the subject, and we will be better off for it."

HENRY DOLGER, M.D., New York.

NOTE.—The letter was referred to Dr. Joslin, who replies:

*To the Editor:*—No one in the world probably appreciated the significance of Dr. Dolger's work on the prevalence of vascular damage in diabetes more than I. Most unfortunately I missed that error in the proof and the figure "20" instead of the correct figure of "200" cases went into the published text, although my duplicate of the text shows my paper had the correct figure.

It may be of interest to the readers that Dr. Dolger's comment was a challenge to us all, and now we have 5 of our own cases, 1 case from the University of Iowa at Iowa City and another from the Mayo Clinic, in which the patients have lived not twenty years, but twenty-five years with diabetes and show no sign of degenerative disease in the eyes, in the heart, in the kidneys or in the aorta (including lateral roentgenograms), in the pelvic arteries and vessels of the legs.

Dr. Dolger's work was most stimulating, and when a sufficient number of these exceptional cases are collected, it will be of great value to trace the treatment they have followed during their quarter century or more of diabetes.

ELLIOTT P. JOSLIN, M.D., Boston.

## FLUORESCEIN

*To the Editor:*—I was most interested in the work of Menaker and Parker, "Fluorescein: An Adjunct in Surgery of Extrahepatic Biliary Passages," in THE JOURNAL of Dec. 4, 1948. Dr. C. J. Sutro and myself did the same thing many years back. This work was collateral to the use of filtered ultraviolet radiation in orthopedic pathology. The references to our publications are these:

1. Visualization of the Biliary System by Fluorescence: *Results of Animal Studies Following Intravenous Injection of Mercurochrome-220 Soluble or Direct Injection of the Dye Into the Gall Bladder, J. A. M. A.* **99:** 2024 (Dec. 10) 1932.

2. Examination of Tubular Organs and Arterial Systems of Rabbits by Filtered Ultraviolet Radiation, *Arch. Surg.* **28:** 867-873 (May) 1934. Photographs of the gallbladder, the extrahepatic biliary ducts and duodenum before and after exposure to filtered ultraviolet radiation were shown.

3. Practical and Experimental Uses of Fluorescein in Medicine, *Arch. Phys. Therapy,* **16:** 71-73, 1935.

The late Dr. Philip Grausman, attending surgeon of the Hospital for Joint Diseases, injected at our request 20 cc. of a 0.06 per cent watery solution of acriflavine into the gallbladder of each of 2 patients before the gallbladder was removed. The dye fluoresced a golden yellow under filtered ultraviolet radiation in the darkened room. The common duct and the second portion of the duodenum were outlined well. Dr. Grausman supplied us with fluorescein powder for further investigation, especially the intravenous injection of a fluorescein solution. (Fluorescein is the mother substance of merbromin ["mercurochrome"]). This was not done because of the press of other work.

It is to Lange's credit that he demonstrated the value of fluorescein in the study of circulatory adequacy. The good work of Menaker and Parker is equally applicable in the surgery of other tubular structures.

MICHAEL BURMAN, M.D., New York.

## VAGOTOMY FOR PEPTIC ULCER

*To the Editor:*—The report of Drs. Paulson and Gladsden (THE JOURNAL, January 15, page 151) involves a problem of interest to those surgeons performing vagotomy for the therapy of peptic ulcer and to other scientists who attempt to explain the results of this operation. Paulson and Gladsden report that the pyloric sphincter as well as the remainder of the stomach becomes more relaxed after vagotomy and that the delayed gastric evacuation resulting from this operation cannot be due to pylorospasm. This report emphasizes the fact that the physiology of the sphincter is of clinical as well as academic interest.

Many investigators, employing rather indirect experimental methods, have concluded that the pyloric sphincter reacts in a manner opposite to the remainder of the stomach. Paulson and Gladsden emphasize that if this were true, vagotomy, which depresses gastric tone and motility, should stimulate the sphincter and retard gastric evacuation by producing pylorospasm.

Since 1937 our laboratory has employed a variety of rather direct methods of studying the sphincter and has uniformly observed that in regard to its motor activity, the gastroduodenal region (antrum, sphincter and bulb) behaves as a unit. Contrary to older reports, all three regions are similarly inhibited by the presence of fats, fatty acids or hydrochloric acid in the upper intestine or by pain and other noxious impulses or by drugs which block parasympathetic nerves. We also demonstrated that the delayed gastric emptying associated with these factors results from a decrease in antral pumping activity and occurs in spite of a relaxed pyloric sphincter.

Thus, the fact that vagotomy delays gastric evacuation and also relaxes the sphincter as Paulson and Gladsden have demonstrated by an acceptable method (gastroscopic observation) is not "surprising." Actually, it is in accord with the newer knowledge obtained by other critical technics and it confirms the modern evidence that the behavior of the sphincter is similar to and not contrary to that of the adjacent portions of the digestive tract.

J. P. QUIGLEY, PH.D.
DANIEL A. BRODY, M.D.
The University of Tennessee.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Various Centers. June 20-22, Sept. 12-14. *Part II.* April 25-26. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY, INC. *Written.* Various Centers. July 15: Final date for filing application is April 15. *Oral.* April 10-14 and Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, INC.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY. *Part I.* Various Centers. *Part II.* New York City, Jan. 1950. Sec., Dr. Harold A. Sofield, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PATHOLOGY: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

AMERICAN BOARD OF PEDIATRICS: *Oral.* Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

AMERICAN BOARD OF PHYSICAL MEDICINE: Atlantic City, June 4-5. Final date for filing application is March 1. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC. December, New York City. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY. Atlantic City, June 2-4. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY. *Written.* Various Centers, March and October. Final date for filing application for October examination is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

ALASKA: * Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

ARKANSAS: * Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Examination,* Los Angeles, Feb. 28-March 3. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

COLORADO: * *Endorsement,* Denver., April 5. *Written,* Denver, June 20-22. Sec., Dr. W. W. King, 831 Republic Bldg., Denver 2.

CONNECTICUT: * Hartford, March 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

DELAWARE: Dover, July 12-14. Sec., Dr. J. S. McDaniel, 229 South State St., Dover.

DISTRICT OF COLUMBIA: * *Reciprocity,* Washington, March 14. *Written,* Washington, May 9-10. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., Washington.

FLORIDA: * *Examination,* Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

GEORGIA: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

GUAM: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

ILLINOIS: Chicago, April 12-14. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

INDIANA: *Examination.* Indianapolis, June. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

IOWA: * *Examination.* Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KANSAS: Kansas City, June 1-2. Sec., J. F. Hassig, 905 North 7th St., Kansas City, Kans.

KENTUCKY: *Examination.* Louisville, June 15-17. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

MAINE: Portland, March 8-9. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

MARYLAND: *Examination.* Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

MASSACHUSETTS: *Examination.* Boston, March 8-11. Sec., Dr. George L. Schadt, 413 E. State House, Boston.

MINNESOTA: * Minneapolis, April 19-21. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

MISSOURI: *Examination.* St. Louis, May 30-31 and June 8-10. Exec. Sec., Mr. John A. Hailey, Box 4, Jefferson City.

MONTANA: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

NEBRASKA: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

NEVADA: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

NEW HAMPSHIRE: Concord, March 10-11. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination.* Trenton, June 21-24. Sec., Dr. E. H Hallinger, 28 West State Street, Trenton 8.

NEW MEXICO: * Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

NORTH CAROLINA: *Endorsement.* Pinehurst, May 9. *Examination.* Raleigh, June 23-25. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

OHIO: *Endorsement.* Columbus, April 5. *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OREGON: * *Endorsement.* Portland, April 29-30. *Examination.* Portland, July. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

PENNSYLVANIA: *Examination.* Philadelphia and Pittsburgh, July. Acting Sec., Mrs. B. G. Steiner, 351 Education Bldg., Harrisburg.

PUERTO RICO: *Examination.* Santurce, March 1. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

RHODE ISLAND: * *Examination.* Providence, April 7-8. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: *Examination.* Columbia, June 27-29. *Endorsement.* Columbia, March 7, April 4, May 2, June 27-28, Aug. 1, Sept. 5 and Oct. 3. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA: * *Examination.* Pierre, July 19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

TENNESSEE: * *Examination.* Memphis, March 23-24. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

TEXAS: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb. 209 Medical Arts Bldg., Fort Worth 2.

UTAH: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VIRGINIA: *Examination.* Richmond, June 17-18. *Reciprocity.* Richmond. June 16. Dr. K. D. Graves, 631 First St., S.W., Roanoke.

WEST VIRGINIA: Charleston, April 7-9. Sec., Dr. N. H. Dyer, State Capitol, Charleston 5.

WISCONSIN: * *Examination.* Milwaukee, June 28-30. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: Cheyenne, June 6. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

Dr [illegible] Bldg., East, Washington.
[illegible] une 11. Sec., Mr. M. W. Emmel.
Ur [illegible]

MICHIGAN: *Examination.* Detroit and Ann Arbor, May 13-14. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

MINNESOTA: *Examination.* April 4, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

NEW MEXICO: *Examination.* Santa Fe, March 20. Sec., Miss Marguerite Kilkenny, 110 W. Houghton St., Santa Fe.

OKLAHOMA: April 15. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Portland, March 5, June 18, Sept. 3 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

SOUTH DAKOTA: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, March 21-22 and July 8-9. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

WISCONSIN: Madison, April 2. Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American Journal of Medical Sciences, Philadelphia

Effect of Oral Caronamide [Carinamide] on Plasma Penicillin Levels Following Large Intramuscular Doses of Penicillin. A. O. Seeler, H. S. Collins and M. Finland.—p. 241.
*Plasma Penicillin Levels After Oral Penicillin With and Without Oral Caronamide. H. S. Collins, A. O. Seeler and M. Finland.—p. 248.
*Poliomyelitis in Families Attacked by the Disease: I. Distribution of Virus in Stool and Oropharynx of Members in Households. H. A. Wenner and W. A. Tanner.—p. 258.
Maintenance of Patients with Tropical Sprue by Means of Massive Doses of Synthetic 5-Methyl Uracil (Thymine). G. G. Lopez, F. Milanes, R. L. Toca and others.—p. 270.
Healing of Resistant Skin Ulcers After Treatment with Nitrogen Mustard: Preliminary Note. J. Aleksandrowicz.—p. 275.
Therapy of Acute Fluoride Poisoning. J. H. Peters.—p. 278.
*One Hundred Cases of Miliary and Meningeal Tuberculosis Treated with Streptomycin. P. A. Bunn.—p. 286.
Evaluation of Thymol Turbidity Test. R. G. Ernst and L. B. Dotti.—p. 316.
Sickle Cell Trait. Incidence and Influence in Pregnant Colored Women. P. K. Switzer and H. H. Fouché.—p. 330.
Hamartomas of Lung and So-Called "Pulmonary Adenomatosis." M. A. Simon.—p. 333
Tropical Environment and Communicable Disease. G. E. Gordon and D. L. Augustine.—p. 343.

**Carinamide and Plasma Penicillin Levels.**—Studies on the effect of carinamide on the blood levels obtained during oral administration of penicillin are the subject of this report by Collins and his associates. They found that penicillin when administered orally alone in doses of 100,000 units every four hours could not be relied on to maintain significant concentrations of the antibiotic in the plasma in persons under 60 years of age. Penicillin levels of 0.03 unit per cubic centimeter were usually maintained in persons over 60 years old on the same dosage. Carinamide in oral doses of 4 Gm. every four hours in persons under 60 and in doses of 3 Gm. every four hours in those over 60 enhanced and prolonged the levels from orally administered penicillin. In patients older than 60 years with slightly elevated blood nonprotein nitrogen levels the enhancing effect of carinamide persisted for at least twenty-eight hours after the carinamide was discontinued. This effect was associated with persistence of significant carinamide concentrations in the blood of these patients. The enhancing effect of carinamide on plasma penicillin levels when the penicillin is given orally seemed to be less than was the case when penicillin was given intramuscularly. The effects of carinamide during oral administration of penicillin appear to be more erratic and the individual variations are even greater than when penicillin is given intramuscularly. That age alone has an enhancing and prolonging effect on penicillin blood levels was shown in previous studies.

**Distribution of Poliomyelitis Virus in Families.**—Wenner and Tanner call attention to the widespread distribution of poliomyelitis virus in certain households attacked by the disease. Their studies were made on five families. Of 24 members of these families 17 (13 children and 4 adults) had poliomyelitis virus in their intestinal discharges and in 7 (5 children and 2 adults) virus was detected in the throat. On the basis of history of onset of illness and isolation of poliomyelitis virus in members of four of the five households it is suggested that virus was seeded in respective members at a common source.

**Streptomycin in Miliary and Meningeal Tuberculosis.**—Bunn presents the results obtained with streptomycin in 100 patients with proved acute miliary tuberculosis and/or tuberculous meningitis who were treated in the course of thirteen months in forty-seven Veterans Administration Hospitals and in five civilian hospitals. Forty of these patients are still alive between 4 and 14.3 months following the initiation of treatment. The *pulmonary dissemination* of miliary tuberculosis proved the most responsive to streptomycin, but a considerable number (37 per cent) of patients with tuberculous meningitis have also survived. These results are interpreted not so much as meaning that streptomycin can cure these two types of disease but rather as indicating that it is capable of influencing favorably the course of tuberculosis.

Residual Effectiveness of DDT in Third Season After Application. W. G. Downs, R. Colorado Iris and J. B. Gahan.—p. 741.

**Para-Aminobenzoic Acid and Murine Typhus.**—Sadusk and his associates believe that the mechanism of action of para-aminobenzoic acid is primarily rickettsiostatic. They found that administration of para-aminobenzoic acid in adequate dosage to guinea pigs infected with murine typhus generally prevents the development of fever and scrotal reaction but permits the appearance of rickettsias in the circulating blood and the formation of complement-fixing antibodies. This rickettsemia appears in the treated animals at the same time as that observed in untreated infected animals. Complement-fixing antibodies also appear at the same time in both groups of animals, and the rise in titer likewise is about the same. Despite the fact that animals treated with para-aminobenzoic acid may exhibit no signs of clinical infection, such animals are immune to subsequent challenge with murine typhus rickettsias.

Study of Certain Problems in Use of Standard Tuberculin. Fractionation of PPD, Standardization of Tuberculins, and Question of Sensitization. Florence B. Seibert and Emma Dufour.—p. 363.

**Vaccination Against Tuberculosis.**—According to Aronson BCG vaccine was administered intracutaneously to 1,551 American Indians ranging in age from less than 1 year to 20 years and to 123 newborn infants. At the same time 1,457 Indians of comparable age and living under the same conditions received an intracutaneous injection of sterile isotonic sodium chloride solution and served as controls. One hundred and thirty-nine newborn infants also served as controls. The vaccinated persons and controls were followed over nine to eleven years by means of tuberculin tests and roentgenograms of the chest, while the group of "newborn" infants was similarly followed for six to eight years. Among the 1,551 persons vaccinated with BCG there occurred a total of 55 deaths, including 6 deaths from tuberculosis. Among the 1,457 controls there occurred a total of 109 deaths, including 53 deaths from tuberculosis. Among the 123 newborn infants who were vaccinated 7 have died, none from tuberculosis. Among the 139 newborn controls, 15 have died, 4 of them from tuberculosis. The tuberculin reaction became positive one year after vaccination in 93.3 per cent of cases and has remained at approximately the same level throughout the course of study. Among the controls the tuberculin reaction became positive in 12.7 per cent within one year after the initial negative reaction, and there has been a constant and gradual increase in the percentage of the controls reacting to tuberculin. Roentgenologically demonstrable lesions having the characteristics of primary tuberculosis occurred in 22 of the vaccinated and in 120 of the controls. Minimal lesions of reinfection type, progressive lesions and miliary and extrapulmonary lesions of tuberculosis were found in 21 of the vaccinated and in 93 of the controls.

**Rare Tubercle Bacilli in Sputum.**—Pottenger says that at his sanatorium the dilution-flotation-picric-acid technic has been employed for the examination of sputum. By examination of three day specimens every six weeks it has not been possible to demonstrate an absence of bacilli for three consecutive examinations in more than 4 or 5 per cent of the patients at the time of discharge from the sanatorium. In contrast, many institutions report sputum conversion in 50 per cent or more. The author raises the question: "How dangerous is sputum which contains a few hundred or a few thousand bacilli in a twenty-four-hour quantity?" The "rare bacillus" stage of tuberculosis, with the discharge of a few hundred or a few thousand bacilli per day, is compared with the acute stage in which millions and even billions of bacilli are discharged per day. There is a question whether patients with chronic destructive lesions would even become continuously and permanently free from the discharge of bacilli, if technics for examination were sufficiently sensitive, even though the patients might be clinically well and able to carry on their regular work. As about two thirds of clinical patients give no history of association with "open" tuberculosis, the importance of susceptibility is compared with that of environment in causing illness. The author stresses the importance of reducing susceptibility through both vaccination and improvement in environment.

**Streptomycin-Resistant Tubercle Bacilli.**—Bernstein and his co-workers treated 45 patients who had pulmonary tuberculosis with 1 Gm. of streptomycin daily, divided in five or six equal doses, for a period of one hundred and twenty days. Tubercle bacilli isolated prior to therapy from all 45 patients were sensitive to 1.0 microgram or less of streptomycin per cubic centimeter of medium. After one hundred and twenty days of treatment with streptomycin, tubercle bacilli were recovered from the sputum or gastric contents of 31 of the 45 patients. Tubercle bacilli resistant to 10 or more micrograms of streptomycin per cubic centimeter were recovered from 26 of the 31 patients. Eighteen strains were capable of growth in over 1,000 micrograms of streptomycin per cubic centimeter of medium. The rate of development of streptomycin-resistant tubercle bacilli was greatest during the second month of therapy.

Gastroenterology: Review of Literature from July 1946 to July 1947. J. B. Kirsner, W. L. Palmer, W. E. Ricketts and others.—p. 534.

**Temporal Arteritis.**—Crosby and Wadsworth believe that benign arteritis and periarteritis of the temporal arteries are not as uncommon as the paucity of reported cases would indicate. The 2 cases here reported have been seen at the Eastern Maine General Hospital within a six month period. Three additional cases seen at the Joseph H. Pratt Diagnostic Hospital in Boston are briefly reported. This brings the total of reported cases to 48. The essential data of previously reported cases are analyzed. The pathologic changes in biopsy specimens of artery segments of 1 of the reported cases are described in detail. A dissecting aneurysm of one temporal artery and phlebitis of the accompanying veins were found. From the analysis and study of the clinical and pathologic data of all the reported cases it is apparent that temporal arteritis is a distinct clinical entity affecting persons of the older age group and characterized by local symptoms consisting of painful, tender, red, swollen, nodular and thrombosed temporal arteries with edema and pain in the adjacent structures and systemic symptoms consisting of fever, malaise, anorexia, loss of weight and weakness. The edema of the overlying skin is probably contributed to by phlebitis of the accompanying vein. Blindness is relatively common in this disease and was found in one or both eyes in 33.3 per cent of the cases. The possible prophylactic value of section of the middle temporal artery early in the disease is suggested. The local symptoms can be explained on the basis of inflammation of the temporal vessels and their branches. The systemic symptoms probably indicate a more generalized arteritis. The mortality of this disease, 12.5 per cent, is considerably less than that of most other forms of arteritis.

**Seedbed of Tubercle Bacillus.**—Medlar and his co-workers point out that the steady decline in the mortality from tuberculosis has been interpreted as indicating that this disease would in the near future become one of minor significance. This implies that there is a definite ratio between new cases of tuberculosis and deaths from the disease. Studies indicate, however, that the mortality rate and the annual incidence rate are independent. The present study was undertaken to determine the unknown source of infection, the "seedbed" of the tubercle bacillus. The authors found that among patients who died from tuberculosis the clinical diagnosis was incorrect six times more often for persons over 50 than for persons under 30 years. Among patients who died from other diseases, but who harbored tuberculosis which was capable of spreading, there was clinical recognition of tuberculosis in only one fourth. Older persons can have progressive disease with so few manifestations of illness that they may remain unrecognized spreaders of the infection. The registration of death from tuberculosis in New York City appears to be below the actual with respect to persons over 50 years of age. In a high proportion of new cases of tuberculosis the disease is apparently contracted from unrecognized sources of infection. Mortality rates, encouraging as they seem, do not indicate either the extent or the location of the seedbed in which the tubercle bacillus resides. The seedbed must be controlled if the continuity of the disease is to be broken.

Preliminary Report on Rheumatic Fever in Virginia. Carolyn M. McCue and Louise F. Galvin.—p. 467.

**Transfusion in Newborn Infants.**—Recent literature contains reports on giving transfusions to the newborn infant via the umbilical vein within the umbilical cord. The applicability of the method is limited by the brief period during which the umbilical vein remains patent within the rapidly atrophying cord. Estimates of this period vary between twelve and forty-eight hours. Pinkus utilized that portion of the umbilical vein which lies within the abdominal wall. Here the vein is readily available even after atrophy of the umbilical cord. A transverse incision is made cephalad to the upper margin of abdominal insertion of the umbilical cord. The umbilical vein is visualized as a whitish, longitudinal, tubular structure elevating the thin midline aponeurosis. A 0.5 cm. longitudinal incision through the aponeurosis is made on either side of the vein. After loose application of a fine silk or a surgical gut ligature around the upper exposed portion of the vein, a transverse nick is made through its anterior wall. A cannula is then introduced cephalad until blood can be aspirated. The ligature is then tied with a single hitch to effect snug approximation of the vein wall around the indwelling cannula, and transfusion is carried out. On termination of transfusion, the cannula is withdrawn, and the ligature is tightened and completed with a second hitch. Skin edges are approximated with two silk sutures. The length of time after birth during which this technic is applicable is as yet undetermined, but its usefulness far outlasts the approach via the cord

Ragweed Extermination Plan for Philadelphia: Results of First Year's Survey. G. I. Blumstein, J. Spiegelman and V. Hirsch.—p. 39.
Cancer Situation in Pennsylvania. L. D. Bristol.—p. 45.

**Gold in Rheumatoid Arthritis.**—Cohen and his associates gave seven hundred and twenty-one courses of gold therapy in 475 patients with rheumatoid arthritis. The same gold preparation was used in all cases. In the earlier cases a course of gold therapy consisted of intramuscular injections of 10 mg. twice weekly, four doses; 25 mg. twice weekly, four doses; 50 mg. twice weekly, four doses, and 100 mg. weekly, nine doses—a total of 1,240 mg. At present the course consists of 10 mg. twice weekly, four doses, and 25 mg. twice weekly, four doses; if improvement is shown at this point, the dosage is not increased, and 25 mg. is given weekly until a total of 790 mg. is administered; but if there is no improvement, 50 mg. is given twice weekly, four doses, 50 mg. weekly, nine doses—a total of 790 mg. The 100 mg. dose has been discarded entirely. This tendency toward lower dosage has increased the safety of gold therapy. Gold therapy resulted in definite objective improvement in 64 per cent. Toxic reactions were encountered in 15 per cent of the courses, 21 per cent of the patients. The authors conclude that gold therapy may be employed in rheumatoid arthritis with safety if conservative dosage is used, if vigilance against incipient toxic reactions is maintained, and if treatment is stopped and the antidote BAL is employed immediately on appearance of the first toxic symptoms.

## Plastic & Reconstructive Surgery, Baltimore

### 3:517-632 (Sept.) 1948. Partial Index

Nasal Deformities of Syphilitic Origin. V. H. Kazanjian.—p. 517.
*Wet Dressings in Plastic Surgery. W. S. Kiskadden and A. J. McDowell.—p. 524.
*Reconstruction of Thumb by Transposition of Adjacent Digit. R. C. Tanzer and J W. Littler.—p. 533.
*Reconstruction of Fingers. G. Nieto Cano.—p. 548.
Plexiglass Splints: Their Use in Pedicle Flap Attachments. G. S. Letterman.—p. 553.
Reduction of Massive Breast Hypertrophy. H. O. Bames.—p. 560.
Mandibular Bone Grafts. W. B. Macomber, R. A. Shepard and V. E. Crofut.—p. 570.
Polyethelene in Reconstructive Surgery. L. R. Rubin, G. W. Robertson and R. N. Shapiro.—p. 586.
Reconstruction of Nasal Tip: New Technic. R. C. Seeley.—p. 594.

**Wet Dressings in Plastic Surgery.**—Kiskadden and McDowell first cover the graft with only one or two single layers of gauze. Irrigating catheters, which may be old no. 16 to no. 20 urethral catheters with extra holes cut in them, are spaced about 2 to 3 inches (5.1 to 7.6 cm.) apart. They are then covered with several layers of moistened gauze sponges and one or two layers of abdominal pads or mechanic's waste. This dressing is then tied snugly in place over the graft by means of heavy silk sutures placed in the skin margins about the periphery of the wound. This dressing is then supplemented with an outer dressing of abdominal pads or mechanic's waste. The use of cellophane, oiled silk, rubber sheeting or other impervious materials is avoided, since it appears to promote the growth of pyocyanic and other infection. The success of the dressing depends on keeping it constantly and thoroughly saturated. Three ounces (90 cc.) of solution injected into each catheter every two hours day and night usually will be adequate. Old third degree burns that when first seen are grossly infected from prolonged improper care can often be grafted within three or four days with no other preparation than the application of wet dressings and correction of existing anemia with blood transfusions. This program presupposes the complete excision of the granulating surfaces and scar base down to normal tissue at the time of operation and the application of relatively thick grafts. Continuing the wet dressing for seven to ten days postoperatively results in a complete take of the grafts.

**Reconstruction of Thumb.**—According to Tanzer and Littler a satisfactory reconstruction of the thumb should meet three criteria: (1) sufficient forceful flexion and extension to permit grasping, (2) opposability of the tip of the reconstructed thumb to the pulp of at least one digit and (3) tactile sensation at its tip. The authors describe a method for the reconstruction of subtotal or total loss of the thumb, which meets these requirements. They present 7 cases in which this method was used. In most cases the transposition of an adjacent digit to thumb position requires the use of a pedicle flap to close the intervening defect It is preferable to perform the transposition and the bony fusion in separate stages in order to obtain a more accurate positioning of the reconstructed thumb. Following fusion, further revision in the nature of tendon transfers and grafts or shortening of the tip is frequently necessary. A damaged digit can often be more effectively employed in reconstructing a thumb than in attempting to restore its useful function as a finger.

**Reconstruction of Fingers.**—Nieto Cano reports the case of a factory worker, aged 21, all 5 fingers of whose right hand had been smashed. Surgical cleansing of the wound left the first and fifth fingers without skin over part of the last phalanges and the second, third and fourth fingers with only the proximal extremities of the first row of phalanges. The author took a piece of bone off the crest of the ilium in order to build up the skeleton of the three phalanges. The piece of bone so obtained has both compact and cancellous tissue. Over the sternum, the author made a Gillies tubed pedicled flap in order to cover the first phalanx of the middle finger and the artificial extremity of the same. He also made pockets under the skin for the second and fourth fingers. Skin grafts were made over the exposed areas of the first and fifth fingers. Except for the loss of the bone graft applied to the index finger the results were as intended.

*Significance of Ulcerating Lesion in Stomach After Gastro-Enterostomy. H. K. Gray and K. A. Lofgren.—p. 454

**Ulcerating Gastric Lesions After Gastroenterostomy.**—Gray and Lofgren reviewed the records of 825 consecutive patients seen at the Mayo Clinic during the ten year period from 1938 to 1947 inclusive, for those in whom a previously made gastroenteric stoma for duodenal or gastric ulcer had to be taken down owing to subsequent complications and for whom partial gastrectomy was performed as a secondary procedure. These subsequent complications for which surgical intervention was advised included jejunal ulceration near the gastroenteric stoma, malfunctioning gastroenteric stoma, gastric ulcer and gastric carcinoma, in descending order of relative occurrence. There were 41 gastric lesions that developed after gastroenterostomy for duodenal ulcer, of which 11 were gastric carcinomas and 30 were benign gastric ulcers. There also were 11 gastric lesions that developed or were retained after gastroenterostomy for gastric ulcer, of which 6 proved to be malignant and 5 proved to be benign gastric ulcer at the time of the subsequent gastric resection. Included in this study was 1 patient whose history showed that he had undergone gastroenterostomy for no demonstrable ulcer and in whom there developed a gastric carcinoma that required surgical intervention several years later. This review proves that lesions that develop in the stomach after gastroenterostomy has been performed have a high incidence of malignancy. Of the 53 patients in whom gastric lesions developed that required secondary gastrectomy, 18 had gastric carcinomas. The true nature of a lesion in a stomach on which gastroenterostomy has been performed is often difficult to determine clinically. The symptoms and clinical findings may give the impression of a benign lesion when the underlying condition is malignant.

**Is Mortality Due to Diabetes Increasing?**—Moriyama shows that the official mortality statistics for the United States *give no indication of the decline in diabetes mortality* which was expected after the discovery of insulin in 1922. On the contrary, the recorded crude death rate for diabetes has continued to rise. Data are presented which suggest that since the introduction of insulin the "true" diabetes mortality trend has been downward rather than upward. The author believes that this discrepancy can be explained by the fact that in the present method of selecting the primary cause of death, cognizance is not taken of the distinction made in the physician's statement that a particular cause was not related to the immediate or underlying cause of death but might have contributed to the risk of dying. In the case of diabetes this frequently results in primary cause assignments that cannot be justified on a medical basis. For example, a physician in attendance on a diabetic patient with heart disease may feel that the diabetes was a contributory factor to the risk of dying even though diabetes was under insulin control. In such a case, he would report the heart disease as the underlying cause of death and the diabetes as a contributory cause. In the cause of death classification, however, diabetes would be selected as the primary cause over heart disease. The author is convinced that unless the cause of death coding practice is modified in regard to diabetes, death statistics will continue to be a misleading index of the mortality risk from diabetes.

**Causation of Acute Pancreatitis.**—Lium and Maddock believe that two factors are responsible for most cases of pancreatitis, (1) obstruction of the pancreatic ducts in the presence of a (2) secreting or stimulated gland. In the experiments described in this paper it was the object first to obstruct the pancreatic ducts and then to stimulate the gland by various means. Stimulation of the pancreas has been produced by (1) feeding, (2) acetylcholine and physostigmine, (3) pilocarpine, (4) stimulation of the vagus and (5) secretin. In a high percentage of these experiments, combining obstruction of the pancreatic ducts and stimulation of the gland, acute inflammation of the pancreas and fat necrosis resulted. The most extensive and consistent damage resulted when the animals were fed two hours before ligation of the pancreatic ducts. The authors discuss the different mechanisms that can produce obstruction of pancreatic secretion. They correlate the clinical and experimental evidence to explain the varying degree of acute pancreatitis seen at operation or necropsy.

**Streptomycin in Contaminated, Sutured Wounds.**—Kirby and his associates say that streptomycin, with fewer limitations than the sulfonamide compounds and penicillin, appears to be a more suitable agent for application to wounds. It has a wide antibacterial range, being effective against both gram-positive and gram-negative organisms. It acts rapidly in the presence of blood and pus and is relatively nontoxic. In the experiments herein reported, sutured wounds produced in dogs have been inoculated with a standard dose of gram-positive and gram-negative organisms, a method resulting in 100 per cent wound infection and 53 per cent mortality in control animals. Prophylactic systemic (intramuscular) administration of streptomycin was effective in controlling the infection, as evidenced by a reduction in mortality, toxicity and septicemia. A single local application of 50,000 units of streptomycin in an ointment base appeared to be as effective as intermittent intramuscular administration for six days. This was true both when the streptomycin was applied locally at the time of inoculation with the organisms and when applied eight hours later after multiplication and invasion of the bacteria had begun. The occurrence of streptomycin-resistant organisms in many human traumatic wounds would be expected to limit the clinical effectiveness of streptomycin in the ointment base used in these experiments. In addition, the ointment base causes separation of the wound edges and acts, to some extent, as a foreign body.

**Chronic Suppurative Tympanomastoiditis.**—Sellers points out that chemotherapy and biotherapy have reduced to almost zero the incidence of acute suppurative mastoiditis. Various bacterial forms develop an immunity to these therapeutic agents when the agents are used in insufficient dosages and over insufficient periods. When immunity of the bacteria occurs in acute otitis media, the infection will become latent, the pathologic process will continue at a reduced pace, and chronic tympanomastoiditis will develop. Cases of chronic tympanomastoiditis usually stem from acute suppurative otitis media rather than from acute suppurative mastoiditis. As a result of the attempted arrest and repair, varying portions of the tympanum, attic and antrum, and usually a greater or lesser portion of the mastoid are involved in varying degrees. For this reason treatment must be determined by the distribution and type of lesion. Here lies the difference between acute suppurative otitis media and mastoiditis on the one hand and chronic suppurative tympanomastoiditis on the other. In acute suppurative mastoiditis (if no complications exist) the problem is the same in every case. It is the elimination of an acute suppurating focus. Each case of chronic tympanomastoiditis presents a problem of its own. The treatment of tympanomastoiditis is not necessarily surgical; under certain conditions medical treatment may be sufficient. Surgery should be advised and even urged when any of the following factors are present: (1) an active process in the mastoid, (2) an incarcerated cholesteatoma, (3) evidence of progressive necrosis in the tympanum or attic, (4) evidence of the extension of the process to the internal ear, the facial nerve or the intracranial cavity and (5) evidence of increased sepsis. The author stresses that because in the future chronic tympanomastoiditis will be the infectious disease of the temporal bone most frequently encountered, ability to perform the total or modified tympanomastoidectomy must be brought to its best technical development. In the author's hands the endaural approach has proved to be the more satisfactory.

**Inflammatory Lesions of Bone Resembling Neoplasms.**—Breck and his co-workers say that sometimes it is astounding how much an inflammatory lesion can resemble a bone tumor. They report 3 cases in which the differentiation was impossible clinically and roentgenologically. In 2 of these cases a tumor was believed to be the most likely diagnosis and an inflammatory process was considered in the differential diagnosis. In the third case a neoplasm was the only diagnosis seriously considered. One of these cases looked much like Ewing's tumor of the shaft of the tibia; the second case looked like an osteogenic sarcoma of the shaft of the metatarsal bone; the third case resembled an osteogenic sarcoma of the end of the fibula in a child. The differential diagnostic points in these cases are brought out by the case histories and discussion. The authors stress the importance of making a careful biopsy before instituting radical treatment in a case of suspected cancer of the bone.

**Laboratory Diagnosis of Chancroid Disease.**—Kuhns and his co-workers show that hitherto the diagnosis of chancroid was usually made by a process of exclusion, which consisted of repeated dark field examinations for spirochetes. If results were negative, diagnosis of chancroid or lymphogranuloma venereum was made, based on clinical manifestation. Chancroid disease was a considerable problem in the occupational troops in the Philippines. A study of contacts reported by Trussell of the Medical Laboratory in Manila indicated that many of the women demonstrated chancroid lesions which were negative for spirochetes on dark field examination; findings on direct smear were typical of Hemophilus ducreyi. Other investigators confirmed the role of H. ducreyi. Various mediums have been used for the culture of the organisms from chancroid lesions. At the laboratory with which the authors are connected it was found that tissue impressions on glass slides properly made and stained from chancroid ulcers consistently demonstrated morphologically characteristic H. ducreyi organisms. Of 40 penile ulcers suspected to be chancroid, 21 were found positive by direct smear; in 34 of the 40 cases cultures were made, and 14 of these were positive for chancroid. It is their experience that the impression smear and culture are reliable. The method of preparation of the lesion for making the smear is essential for success in making a good impression slide and for obtaining cultures of the organism. The authors confirm the value of the tryptose phosphate agar medium. An apparent mutation form of H. ducreyi, hitherto undescribed, has been reported.

**Indiscriminate Use of Estrogens in Menopause.**—Habel points out that the increasing number of patients seen with uterine bleeding due to overstimulation of estrogenic hormones, and a recent article by Ayre, showing a definite relation between nutritional deficiency, excessive estrogens and inflammation as a possible cause of cancer of the cervix, led him to examine some of the effects of the excessive use of estrogens. There has been much controversy on the question of whether estrogenic substances can cause cancer or not, and the general conclusion is that they cannot, if given in the usual therapeutic doses. However, women who have late menopause—that is, between the ages of 50 and 55—are more prone to have adenocarcinoma of the uterus. It has also been stated that a woman experiencing a functional menorrhagia or metrorrhagia at the menopause, particularly a woman with evidence of persisting estrogenic effect in her postmenopausal years, should be regarded as predisposed to the development of adenocarcinoma of the uterus. It has been found that in cases of granulosa cell tumor of the ovary in postmenopausal women the incidence of carcinoma of the uterus is very high. Since this type of tumor causes an abnormal estrogenic stimulation, it is highly suggestive of estrogen-cancer relationship. The author further shows that the excessive use of estrogenic hormone may produce excessive bleeding and that the prolonged use of estrogenic substances will often cause prolongation of the menopause. Addiction enters into the indiscriminate use of estrogens. These undesirable effects can be prevented if patients are carefully selected and such substances as vitamin $B_1$, vitamin E and male sex hormone are substituted for estrogenic substances. Small doses of estrogens given over a short period of time in selected cases are desirable, but self medication should be discouraged.

**Refrigeration in Obstetric Crises.**—According to Allen obstetric hemorrhage is the principal cause of maternal death. Obstetricians of a former generation are said to have used the abdominal tourniquet as a final means of stopping postpartum hemorrhage. The method seems to have been abandoned and forgotten, doubtless because of the possibility of shock, paraplegia or organic damage. The author points out that these dangers can be reduced in proportion to the reduction of temperature. The unconscious or deeply anesthetized woman should be picked up by the feet and legs and held vertically with head down, to let all possible blood flow toward the head and the intestine fall toward the diaphragm. A tourniquet should be applied quickly around the abdomen just above the pelvic bones, and the patient immediately replaced horizontally on the table. A large very elastic pure rubber tube should be applied in several superimposed turns. The aorta and other arteries should thus be easily occluded. The legs and abdomen up to an inch or two above the tourniquet should be completely surrounded by finely crushed ice. Though every effort should be used to make the time of tourniquet application as short as possible, reasonably efficient refrigeration will provide ample time for both transportation and operation, even up to the six hour duration. After surgical hemostasis, when the tourniquet is removed, the body temperature should be raised rapidly to a little below normal.

**Two Hour Pregnancy Test.**—Fried shows that the two hour rapid rat ovary hyperemia pregnancy test is advantageous because of its increased sensitivity and rapidity, the rarity of false positive reactions, the increased tolerance of the rat to toxic specimens of urine and the conveniences of the test and test animals. However, unfavorable features are the false negative reactions and the lack of a sharp positive end point.

*Early Diagnosis of Infective Hepatitis in Syphilitic Patients Undergoing Arsenical Therapy. W. Fowler.—p. 80.

**Early Diagnosis of Infective Hepatitis During Arsenical Therapy.**—According to Fowler, the incidence of infective hepatitis is still great in syphilitic patients undergoing arsenical therapy despite the care taken in venereal disease clinics to avoid dissemination of the causal virus. A diagnosis of hepatitis is seldom made prior to the appearance of bile in the urine, although it can be diagnosed in the preicteric stage by the intradermal histamine test of Kline. Unfortunately early symptoms such as nausea and loss of appetite, which would lead one to perform this test, are frequently so slight as to be disregarded. When examining records of cases of "arsenical jaundice," it was noted that in the majority of cases a loss of weight occurred shortly before signs of jaundice appeared. Attention to the weight of patients on antisyphilitic treatment and the Kline test on patients who lost 2 pounds (907 Gm.) or more within a week revealed that of 64 patients who contracted hepatitis 56 showed a loss of weight of 2 pounds or more seven to ten days before bile appeared in the urine. It is suggested that the use of Kline's test for all patients who show a sudden loss of weight of at least 2 pounds provides an easy and effective method of diagnosing infective hepatitis in the preicteric stage.

**Penicillin in Diphtheria.**—Cruickshank and his associates of the Public Health and Laboratory Service studied the penicillin sensitivity of 284 strains of Corynebacterium diphtheriae isolated in different parts of the country. Most of the strains tested were two or three times as resistant to penicillin as the Oxford staphylococcus. Gravis strains in C. diphtheriae were more resistant to penicillin than intermedius, and intermedius were more resistant than mitis types. All patients with acute diphtheria received antitoxin in doses depending on the severity of the case. A single bath of crystalline penicillin (sodium salt) was used. The standard adult dose was 60,000 units given intramuscularly every four hours during the day time only (daily dosage 240,000 units). Children up to 4 years of age received a third, and children aged 5 to 10 years two thirds, of the adult dose. Children over 10 years were treated as adults. Of 65 patients with acute faucial diphtheria treated with penicillin, 26 of 37 receiving a three day course and 23 of 28 receiving a six day course became free from the infecting organism within four days of the end of treatment. In 31 persistent diphtheria carriers treatment with penicillin was followed by the rapid disappearance of the organism from the throat in only 13 cases.

**Thymine, Folic Acid and Vitamin $B_{12}$ in Anemias.**—Spies and his associates made a comparative study of thymine, folic acid and vitamin $B_{12}$ under controlled conditions on selected patients with macrocytic anemia in relapse. One patient with pernicious anemia, one with nutritional macrocytic anemia and one with tropical sprue were each admitted three times to the hospital and given a diet free from meat and meat products. Base line determinations were made on each admission. Each compound produced a blood response and a definite clinical improvement. The fact that three distinct chemical compounds have proved effective in each of three distinct syndromes suggests that we may learn a great deal about the pathogenesis of these diseases. It appears that several thousand times the weight of thymine is required to produce a response similar to that produced by folic acid and that several thousand times the weight of folic acid is required to produce a response similar to that produced by vitamin $B_{12}$. These findings suggest that vitamin $B_{12}$ is by far the most potent antianemic substance known.

**Exchange Transfusion in Hemolytic Disease of the Newborn.**—Mollison and Cutbush advance the following aims for exchange transfusion in the treatment of hemolytic disease of the newborn: (1) to raise the hemoglobin level rapidly without increasing the blood volume; (2) to reduce to a minimum the amount of breakdown of Rh-positive cells during the critical first four days of life, since it is possible that the blood destruction in this phase is indirectly responsible for the tissue damage, and (3) to provide the infant with such a concentration of Rh-negative cells that no further transfusions will be needed. In their experience this has proved to be the most substantial advantage of exchange transfusion. The percentage exchange effected by withdrawing the infant's own erythrocytes and replacing them with Rh-negative erythrocytes depends on the infant's and donor's initial red cell counts as well as on the total volume of blood exchanged. It is important to secure a good percentage exchange of Rh-negative cells for Rh-positive cells and to leave the infant with a high absolute concentration of Rh-negative cells to tide it over the subsequent forty days or more, during which it is unable to maintain a satisfactory concentration of Rh-positive cells. This objective is best achieved by the use of donor's blood with a count of 5,000,000 to 6,000,000 erythrocytes. The severity of hemolytic disease of the newborn can be assessed reliably from an examination of cord blood. Although the authors have gained a favorable impression of the clinical effects of exchange transfusion, they admit that it has not as yet been proved whether it lowers mortality and morbidity. Since they have observed no ill effect from it, they consider it the most convenient therapeutic method available, but it is not a trivial procedure and should be reserved for cases in which a single transfusion of Rh-negative blood is not likely to suffice.

*Gangrene of the Leg Following High Ligation of Great Saphenous Vein. J. S. T. T. Hill.—p. 238.

**Gangrene of Leg Following Ligation of Saphenous Vein.**—Hill reports the case of a man on whom he performed a high ligation of the left great saphenous vein under general anesthesia. The vein was injected distally with 20 per cent role in the formation of hemoglobin and the red blood cells. The second is the study of thyroid physiology with radioactive iodine. The third, a very important one, presents the pertinent findings of atomic bomb irradiation in the Japanese.

**Essentials of Pathology.** By Lawrence W. Smith, M.D., F.C.A.P., Associate Professor of Pathology, Cornell University Medical School, New York, and Edwin S. Gault, M.D., F.C.A.P., Associate Professor of Pathology and Bacteriology, Temple University School of Medicine, Philadelphia. With a foreword by the late James Ewing, M.D. Third edition. Fabrikoid. Price, $12. Pp. 761, with 710 illustrations. The Blakiston Company, 1012 Walnut St., Philadelphia 5, 1948.

In the third edition of this textbook of pathology the form has been reduced to a conventional size, the text revised and augmented with new material, case histories condensed, repetitious and less important histories omitted, sixty-one new figures added, including four in color, and the bibliography brought up to date. The original format, with the text and illustrative case histories facing a page of photographs, has been retained. The authors have adhered well to their tenet that because of the limited time at the disposal of students today a textbook should be practical and restricted to absolute essentials. As a result, this book is an excellent textbook for beginners in pathology as well as for others who wish quickly to refresh their memories. It was not intended as a reference book for pathologists, some of whom, forgetting this, have criticized the book for its lack of scope and its avoidance of controversial issues. Textbooks might well at times be reviewed by students rather than by teachers. This reviewer, in the course of his teaching, noted that the new edition of "Essentials of Pathology" was widely used in his laboratory despite the fact that it had not been specifically recommended. The students using it did well in the course, many ranked high in the examinations, and several floundering students found in it the solution to their dilemma. With the students foremost in mind, academic pathologists should overlook the omissions of detail and brevity of discussion in this book and accept it as an excellent textbook in that it enables students quickly to develop a firm foundation in clinically applicable pathology.

**Traitement des dermatoses communes: Diagnostic d'après les lésions, schémas pathogéniques, topographie.** Par A. Desaux. Cloth. Price, 1960 francs. Pp. 1300, with 320 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6e, 1948.

This book offers much more than one would expect from the title. It is written in a clear and concise style and not only deals with the skin as an autonomous organ, but correlates the cutaneous organ and its manifestations with the entire field of medicine.

The first part (120 pages) describes the histophysiology of the skin, methods and technics of examination, including "Brocq's Alphabet of Dermatological Lesions" and allergic and biologic tests. The second part deals with the diagnosis and treatment of the common dermatoses, which are classified according to their primary lesions and localization. Rare dermatoses are briefly mentioned.

The book offers a wealth of carefully selected methods of therapy, including physiotherapeutic procedures. Each of the 320 photographs is accompanied by an extensive descriptive text.

The book is written primarily for students and junior dermatologists. The experienced specialist will also find it of value in that it groups and classifies a vast amount of well established and newer forms of therapy. The bibliography is extensive and complete.

**Breast Feeding: A Guide to the Natural Feeding of Infants.** By F. Charlotte Naish, B.A., M.B., B.Ch. Awarded Sir Charles Hastings Clinical Essay Prize, 1947. Oxford Medical Publications. Fabrikoid. Price, $3.50. Pp. 151, with 20 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1948.

This book would have been much easier to review had the author specifically stated its purpose and for whose benefit it was written. If it was written for the medical profession, it is entirely superfluous, full of clichés, devoid of scientific observations and with scarcely an original idea. If written for the guidance of nursing or prospective mothers, it is a mixture of medical and nursery jargon and pseudodoxy, which will hardly meet the requirements of a popular book. Many of its inaccuracies are naive; some of its statements amusing, other subject to challenge. The author has gone to some lengths to belabor the obvious and to omit the essential. The subject could lend itself to an excellent little work for the guidance of mothers or, on a truly scientific plane, for the instruction of practitioners; as it is, it is neither.

Among the more glaring inaccuracies in this little volume are such statements as that an infant should nurse the breast with acute mastitis; that it is dangerous to teach that the breast must be emptied at each feeding; that the rate of growth is so much slowed down in the second six months that there seems little chance, indeed, of making up any lack of chest expansion that is found to exist at the age of 6 months; that it is important to have good early feeding, because of the necessity of distending the child's stomach in infancy, so that it can cope with the questions of food necessary for the growth and vigor of childhood.

In marked contrast, the *Journal of Pediatrics* for November 1948 (**33**:660) has a 6 page article entitled "Breast Feeding," by Samuel Stone and Harry Bakwin, which is a splendid example of how accurately and concisely this subject can be treated. It says much more in 6 pages than Dr. Naish tries to say in 149.

**How to Conquer Your Handicaps.** By Marie Beynon Ray. Cloth. Price, $3. Pp. 336. Bobbs-Merrill Co., 724 N. Meridian St., Indianapolis 7. 1948.

This book is written to honor the pioneers in medicine and surgery who have developed new technics for the disabled; the handicapped who achieved greatness in spite of their handicaps and the organizations which are helping the physicians and handicapped persons become useful citizens. The author states that her purpose is to tell the public in simple, nontechnical language the new developments in medical science for the preservation of man, as so much has been written on methods of destruction.

The development in orthopedic and plastic surgery, the methods used in the rehabilitation of the blind, deaf and those with speech defects and how through medical science the aged may still achieve success are told in an interesting and friendly manner. The book makes available the names of all the great men and women whose handicap contributed to their success, the names of physicians and surgeons and the institutions and organizations devoting their efforts to the development of methods for overcoming the handicaps produced by disabilities.

This book is recommended to physicians who are interested in knowing about the "third phase of medical care," or rehabilitation, and to those with disabilities who desire to conquer their handicaps.

**Recent Advances in the Study of Venereal Diseases: A Symposium.** Held under the auspices of the Syphilis Study Section, Division of Research Grants and Fellowships, National Institute of Health, U. S. Public Health Service in the auditorium of the U. S. Department of Commerce, Washington, D. C., April 8-9, 1948. Chairman, Syphilis Study Section: J. E. Moore. Paper. Price, $1.50. Pp. 341, with illustrations. Published in cooperation with the United States Public Health Service. Venereal Disease Education Institute, 216 North Dawson St., Raleigh, N. C., 1948.

Current investigative studies in human and experimental syphilis, as well as in the minor venereal diseases, are presented in this volume. The statistical analyses of the latest available results in a nationwide study of the treatment of early syphilis with penicillin are as valuable to the internist as they are to the syphilologist and to the public health officer. The presentations of the results of treatment of the various types of neurosyphilis with penicillin alone and with combined malaria and penicillin offer to the neurologist, the ophthalmologist and the internist the latest data on these controversial therapeutic problems. The current status of cardiolipin antigens, which represent a significant advance in serologic tests for syphilis, is presented.

This volume contains a number of individual investigations on which current concepts of diagnosis, epidemiology and treatment of venereal diseases are based. However, this volume is a symposium, and it contains much diversity of opinion. It does not represent a systematized presentation of current studies in the field of venereal diseases.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## TREATMENT FOR TAPEWORM

*To the Editor:*—What is the best treatment of tapeworm (Taenia saginata) in a 2½ year old child weighing 28 pounds (12.7 Kg.)? Please give exact dosage and procedure. Bianca Sender, M.D., New York.

Answer.—The success of therapy of Taenia infections depends largely on careful preparation of the patient to insure an upper digestive tract free of food, which enables the drug used to come in intimate contact with the worm. Children not infrequently vomit the anthelmintics used in tapeworm therapy, which greatly reduces their effectiveness and often necessitates repeated treatments or resort to the duodenal tube for administration of the drug.

*Preparation of the Patient.*—A liquid luncheon but no supper is allowed the day preceding treatment. Water or carbonated drinks can be taken freely, but milk should not be permitted after luncheon.

*Administration of the Anthelmintic:* At 8 a. m., 6 cc. of the following emulsion is administered: oleoresin of aspidium 1 cc. or Gm., powdered acacia 1.5 Gm. and water sufficient to make up to 12 cc. One hour later the second 6 cc. of the emulsion of aspidium should be given. If the child is uncooperative and will not swallow the aspidium mixture or if he vomits it, the drug may be given by duodenal tube. Two hours later (11 a. m.) one flat teaspoonful of magnesium sulfate should be given in a glass of water, to be followed two hours later with a soapsuds enema. All stools resulting from the purge and enema should be passed into a container and examined for tapeworm. Search should be made for its head. Toilet paper should not be thrown into the bedpan, as it makes search difficult and the tapeworm head may adhere to it. The child should rest in bed during treatment.

Hexylresorcinol, which is nontoxic and effective, involves administration of the drug by duodenal tube. It may be substituted for the aspidium mixture. The preparation of the patient and all other details of treatment are the same. At 8 a. m. a mixture of 0.30 Gm. hexylresorcinol and 2 Gm. of powdered acacia in 20 cc. of water is given by duodenal tube. The hexylresorcinol is secured by removing the outer gelatin coating from three 0.1 Gm. crystoids anthelmintic® pills of Sharp & Dohme Company and thoroughly pulverizing the inner pills.

If large sections of the tapeworm are passed but the head is not found, treatment should not be instituted again for two to four months, as it is possible that the head was removed but missed in the stool search. If the head remained in the child, a new tapeworm will grow and eggs and segments will appear in the stool in several months, at which time the child should be treated again.

## "OTTO" PELVIS

*To the Editor:*—What information is available on "Otto" pelvis, particularly as to causation and treatment and its incidence in children? Ernest E. Myers, M.D., Lexington, Ky.

Answer.—Intrapelvic protrusion of the acetabulum or "Otto" pelvis involves the hip joint and is usually seen in adults. It occurs in women twice as often as in men. The cause is obscure, but any condition which results in "softening" of the bone about the acetabulum may permit this deformity to develop. It has not been recognized often in children. Pomeranz published a complete account of this interesting lesion (*J. Bone & Joint Surg.* 14:663-686, 1932).

## SCHOENLEN'S PURPURA

*To the Editor:*—What is the approved treatment for Schoenlein's purpura? My patient is a woman 25 years old. She does not have symptoms except for frequent eruptions of purpuric spots. M. D., New York.

Answer.—Satisfactory treatment for Schoenlein's or so-called allergic purpura is not known. Sensitization to certain foods is thought to be a cause of this type of purpura, but it is seldom possible to prove such a relationship. Spontaneous recovery is common.

## WARTS

*To the Editor:*—In a male patient, aged 20 warts developed around bases and lateral margins of the finger nails. The patient was stationed at an army camp in Georgia. He has been treated by many specialists in dermatology with poor results. The warts are disfiguring and uncomfortable. Some of the finger nails have come off and are starting to be replaced. What do you suggest? M.D., Oklahoma.

Answer.—The long list of remedies recommended for the treatment of warts indicates clearly that all of them may prove to be beneficial in some cases, but not in all cases. The remedies include internal measures such as potassium arsenite solution, protiodide of mercury and magnesium sulfate by mouth; destructive measures such as freezing with solid carbon dioxide, the application of liquid air, cautery, diathermy; the application of either salicylic acid in flexible collodion or a heavy oil such as castor oil; radiation with either roentgen rays or radium; bismuth compound administered intramuscularly or directly under the wart; specific vaccine and hypnosis or some allied measure which depends on suggestion.

It might be well in this case to apply radium to the warts, but it must be applied with skill and caution by one with experience in the method. If such treatment is not available, apply a 20 per cent salicylic acid in flexible collodion once or twice during the day and overnight cover the warts with gauze soaked in castor oil. If a reasonable trial with this method should fail to secure results, bismuth salts may be administered intramuscularly by the same dosage and technic as when it is used for the treatment of syphilis. If necessary, one may resort to a destructive measure such as liquid air, if it is available, or to electrosurgery, although the latter may produce scars. Any of these measures are likely to eradicate the warts; yet it is possible that the warts may persist despite all such treatment. Then the patient will note one day that all of the warts have suddenly disappeared and credit for the cure will go to the last method that was used, even if it had no direct relation to the disappearance of the warts.

## CEREBRAL INJURY

*To the Editor:*—A boy 14 years old was in an automobile accident on July 5, 1948. Nose or ear bleeding or discharge from ears was not apparent. The boy did complain of a slight headache, not localized. The headache grew progressively worse. Examination of spinal fluid on July 20 revealed 24 red blood cells in the field and was otherwise negative. On Aug. 14, 1948 another examination of spinal fluid revealed 9 red blood cells in the field. Headaches still persist. Neurologic examination reveals no abnormality. I have the impression that the boy has subarachnoid bleeding. Are there other tests to substantiate such a diagnosis? What other explanation could be given for the persistent headache? F. Stuczynski, M.D., Brooklyn.

Answer.—Granting that the red blood cells discovered in the spinal fluid on July 20, 1948 were not there because of needle trauma of a vessel, it would appear that there had been some subarachnoid bleeding as the result of the injury on July 5. The hemorrhage into the subarachnoid space must have been slight. Twenty-four cells in the fluid would not have been sufficient to cause visible tinging of the subarachnoid fluid. While the case history states that the boy had no apparent (visible?) injuries, it does not state whether he was dazed or dizzy immediately after the injury. He did have slight generalized headache. The headache has grown progressively worse over a number of weeks but without the development of abnormal neurologic findings.

The combination of symptoms, spinal fluid findings and course as given suggests the possibility of one of two conditions—a subdural hematoma or a persistent cerebral edema. The symptoms of subdural hematoma may or may not become evident within a short period of the time of injury. If the symptoms, which are variable, but most commonly include headache, irritability, dizziness, disorientation, mental dulness and later vomiting and lethargy, develop gradually, the course speaks strongly for a subdural hematoma. Careful, repeated neurologic examinations, including ophthalmoscopic examination, should be made. Often positive neurologic signs cannot be discovered even when there is a subdural hemorrhage, but the symptoms, sometimes mistaken for neurotic ones, and the course point to the diagnosis. The hematoma may be bilateral and is commonly parietal in location. The treatment is surgical and consists of burr hole drainage of the hematoma. The other condition to be considered, persistent cerebral edema, is the result of seemingly minor contusion of the brain with a "vicious circle" edema; i.e., because the cranium does not allow for free swelling of the injured tissue, the drainage of fluid from the area is impaired with some resulting increase in the edema. The effects are noticed particularly if the patient is not kept in bed for a sufficient length of time immediately after injury. Hypertonic intravenous solution (sucrose 50 per cent, 100 cc.) and, possibly, lumbar puncture, removing 20 cc. of fluid, will help, but the chief treatment consists of rest in bed until the edema subsides and free circulatory drainage of the edematous area is established. In the case stated it would be well to keep in mind the possibility of subdural hematoma. Subdural hemorrhages may not organize as do other clots. The limiting membrane may serve as an osmotic wall for the absorption of still more fluid and the hematoma may encroach progressively on the cranial contents.

## PROGNOSIS FOR Rh-NEGATIVE MOTHERS

*To the Editor:*—A 26 year old patient had a healthy baby in January 1948. She is pregnant again, and expected delivery is May 1, 1949. Examination of blood showed an Rh-negative reaction. The husband's blood is Rh positive. Although it is known that an Rh-negative mother may have a perfectly healthy baby, I should like to ask whether the infant should be given a transfusion through the cord with Rh-negative blood immediately after delivery, even before definite erythroblastosis of the infant has been discovered by blood studies. If blood transfusion is performed, should the blood be of the same type as that of the infant?

M.D., Connecticut.

Answer.—Not more than 1 in 20 Rh-negative women married to Rh-positive husbands give birth to infants with erythroblastosis in any pregnancy and the fact that a woman is Rh negative is not in itself reason to contemplate transfusion of the infant. A transfusion through the umbilical cord can be given up to eight or ten hours after birth. Unless definite symptoms of erythroblastosis are present no benefit is to be derived from the administration of blood. It is not a prophylactic measure. If symptoms of erythroblastosis are present and transfusion is given the blood should be Rh negative and of the same blood group as the infant.

## PROCAINE ADMINISTERED INTRAVENOUSLY

*To the Editor:*—Has procaine hydrochloride in 1 per cent solution been used intravenously to check attacks of paroxysmal tachycardia?

Harry H. Brauer, M.D., Sisseton, S. D.

Answer.—Procaine hydrochloride in 1 per cent solution has been used dramatically in restoring normal rhythm in a boy aged 7 years with circulatory arrest due to proved ventricular fibrillation of twenty-seven minutes' duration. Cardiac massage was employed and procaine hydrochloride administered intravenously in two doses, the first one consisting of 3 cc. of 1 per cent solution given fifteen minutes after the cessation of the heart beat and 2 cc. given intravenously eleven and one-half minutes later with restoration of normal rhythm thirty seconds after the second injection. Ventricular fibrillation was proved by electrocardiogram. This case was reported in the August 28 issue of The Journal, page 1575, by Lampson, Schaeffer and Lincoln.

Intravenous administration of procaine has also been used prophylactically and effectively for the prevention and correction of cardiac arrhythmias associated with cyclopropane anesthesia as reported by Kraft in the *Canadian Medical Association Journal* (**57**:350, 1947). For this a 0.1 per cent solution was advised with or without thiopental sodium.

Procaine has also been used intravenously to relieve postoperative pain in the dilute solution of 0.10 per cent. With a stronger solution, toxic effects may result.

For the routine treatment of paroxysmal tachycardia, such therapy seems unnecessary, but in serious cases procaine may prove worth while, although it is not in routine use as yet.

## SULFONAMIDE MIXTURES

*To the Editor:*—I am considering use of a mixture of sulfadiazine two parts with sulfamerazine one part. What is the consensus among authorities regarding use of sulfadiazine alone or in combination with other sulfonamide compounds in the treatment of infants and children?

F. A. Stewart, M.D., Newport, R.I.

Answer.—The purpose of mixtures of sulfonamide compounds is to lessen the toxicity to the kidney from the formation of crystals of the insoluble acetyl derivatives. The observation of Lehr (*Proc. Soc. Exper. Biol. & Med.* **58**:11-14, 1945) that the solubility of a sulfonamide compound in a mixture of sulfonamide compounds is independent of the concentrations of the other sulfonamide compounds present, whereas the therapeutic efficacy is additive, suggests that the optimum mixture consists of equal parts of each sulfonamide drug. The principal advantage of the mixture mentioned in the inquiry is lost by the use of unequal proportions of the two compounds.

Whether or not the use of mixtures of sulfonamide compounds is of any real advantage is controversial. Whereas Lehr maintains there is a decided advantage (*J. Pediat.* **29**:275, 1946; J. A. M. A. **137**:1150, 1948), Zeller and others (J. A. M. A. **136**:8, 1948) and Garb and Janoff (J. A. M. A. **138**:381, 1948) maintain that the advantages are not significant from the clinical standpoint. The papers by Lehr and by Zeller furnish information on dosage, absorption, excretion and toxic reactions.

There is therefore a theoretic advantage to the use of sulfonamide mixtures in children and infants, but whether this advantage is as great as that obtained by the use of sulfadiazine or sulfamerazine alone with the concurrent administration of sufficient alkali to maintain the urine at a $p_H$ of 7.5 or higher remains to be determined.

## SUBSTITUTE FOR TABLE SALT

*To the Editor:*—I have the problem of a practically salt-free diet for both myself and wife. I wonder whether you have a formula for making the substitute salt, which contains other chlorides of potassium, ammonium, etc. I have made up a fair substitute, potassium and ammonium chlorides equal parts with four parts of starch, which answers fairly, but have no doubt that you have a much better formula, and if it is available would much appreciate your advice in this matter.

George A. Skinner, M.D., Berkeley, Calif.

Answer.—The substitute about which you inquired is no doubt a preparation called "neo-curtasal," manufactured by Winthrop-Stearns, Inc. This material seems to be a fairly satisfactory substitute for ordinary table salt, and as you will see from its formula, contains no sodium.

## DIABETES HEREDITY

*To the Editor:*—What is the incidence of diabetes mellitus in children with one diabetic parent?

M.D., Illinois.

Answer.—Since the tendency to become diabetic is probably transmitted through recessive genes, the incidence of diabetes in offspring with one diabetic parent depends on the carrier tendency in the marital partner. In a large series of diabetic persons one parent was found to have the disease in 9 per cent of the cases and neither parent in 91 per cent.

## VENOMOUS BITES AND STINGS

*To the Editor:*—Strong exception must be taken to the advice (The Journal, October 30, page 720) to apply heat for relieving the pain of lizard or spider bites or scorpion stings. The accelerated absorption of poison with hyperemia must increase systemic dangers. As against the total absence of scientific evidence favoring heat, the use of cold is supported by: (1) the known analgesia of refrigeration; (2) the marked delay of absorption, shown by (*a*) retarded absorption of penicillin (Trumper, M., and Hutter, A. M.: *Science*, 100:432, 1944), (*b*) protection of rabbits against fatal quantities of mustard gas (Yudin, S. S.: *Am. Rev. Soviet Med.* 2:4, 1944) and (*c*) radical arrest of intoxication from infected gangrene and burns; (3) the anesthesia which facilitates incisions; (4) the known promotion of drainage by cold, presumably because coagulation of exudate is inhibited, and (5) a single newspaper report of a school teacher who applied ice to a scorpion sting, with complete suppression of all local and general symptoms.

Snake bite presents a more formidable problem, including local tissue necrosis produced by a powerful enzyme in the venom, particularly of the rattlesnake. This enzymic action can be arrested by refrigeration, but too prolonged contact with tissues may result in even greater destruction after the temperature is raised. This is not a hazard with lizards, scorpions, spiders, bees, etc., and with a sufficiently dangerous snake bite the local may be preferable to the systemic risk.

This brings up the old tradition of the tourniquet. My own experiments with snake venom (*South. M. J.*, 31:1248, 1938; *Am. J. Trop. Med.*, 19:393, 1939) were made unsuccessful by the use of an occlusive tourniquet, which is disastrous even at ice temperature and still more so at normal temperature. Poisons such as strychnine and procaine are destroyed rapidly enough so that if a fatal dose is injected in a limb, a tight tourniquet applied and released at suitable intervals can absolutely save life. The fallacy for venom is that its destruction requires more time than is feasible for tourniquet application. There is just one use for an occlusive tourniquet. Snakes kill over 30,000 persons in the world annually, and over 90 per cent of the bites are on the limbs. Antivenin is seldom available in time, and excision can seldom cope with the astonishingly rapid diffusion of the venom. The knowledge should be broadcast that a presumably fatal bite, even from a bushmaster or king cobra, can be countered by immediate application of a tight tourniquet a few inches above the wound. Amputation can then be performed when feasible, perhaps hours later when the limb is completely insensitive. Except in the rare instances of direct injection of venom into a vein, it is always possible thus to save life at the cost of a limb. But since most snake bites are not fatal, and drainage by incision and suction has been proved beneficial, a tourniquet if used should be limited to a light "venous" constriction for promoting this process.

The main conclusion is that refrigeration with ice or the coldest obtainable water should be included in the treatment of snake bite for reducing pain and retarding absorption; and for lesser bites and stings it not only will relieve symptoms but may be practically curative.

Frederick M. Allen, M.D., New York 28.

# RADIOCARDIOGRAPHY AND ITS CLINICAL APPLICATIONS

MYRON PRINZMETAL, M.D.
ELIOT CORDAY, M.D.
RAMON J. SPRITZLER, M.D.
and
WALTER FLIEG, M.D.
Los Angeles

Radiocardiography is a method of recording graphically the passage of radioactive blood through the cardiac chambers by means of a specially constructed ink-writing Geiger-Mueller counter.[1,2] It permits the study of certain hemodynamic functions heretofore not possible.

It is the purpose of this communication to describe the technic of this procedure and to discuss preliminary observations on its clinical usefulness. The method has already been found helpful in the diagnosis and prognosis of a number of cardiac conditions. In some cases information has been obtained which could not be arrived at by any other means. The procedure requires but a simple venipuncture; it does not subject the patient to any unpleasantness and is completed in one to two minutes. According to authorities in the field of radiation, whom we have been able to consult, the method is clinically safe. Radioactive sodium ($Na^{24}$) has a short half-life (14.8 hours) and is rapidly eliminated by the kidneys.

This procedure has now been performed on over 400 patients during the last two years without any noticeable untoward effects.

## METHOD

A carefully shielded Geiger-Mueller tube is placed over the precordium; 0.1 to 0.2 millicurie of radiosodium ($Na^{24}$) is rapidly injected into one of the antecubital veins, and the counts are recorded by means of a newly devised ink-writing counter (fig. 1). The curve thus obtained records the concentration of radiosodium in the structures underlying the tube. Of these structures the heart is the major recipient of the radioactive substance. Zero radioactivity is represented on the baseline of the graph; as concentration of radioactivity increases, the curve rises proportionately.

In the early experiments,[2] we obtained in normal persons both diphasic and monophasic curves. It was difficult to understand this variation until further study revealed that after an ordinary rapid intravenous injection, completed in half a second, it might take as long as twelve seconds before the last trace of sodium 24 had left the vein. This was determined by placing a second counter tube in the axilla over the subclavian vein and measuring the time it took for the vein to empty itself of labeled blood. It is thus easy to understand why, with such great delay in passage of the test material, curves would have poor definition and be monophasic. Efforts were made to overcome this venous lag and to get the sodium into the heart more rapidly and in one compact mass. This, of course, could be accomplished with a cardiac catheter or through injection into the jugular vein. However, such procedures are undesirable because they reduce the simplicity of the method. We did partially overcome the venous lag by (1) warming the extremity before injection, (2) exercising the arm and (3) raising the arm vertically immediately after injection. This latter procedure needs special emphasis, for if the arm is not raised—as was the case in our earlier experiments—the flow of the labeled blood into the superior vena cava and right ventricle may be very sluggish, resulting in R waves of relatively low amplitude with a more slowly rising (less vertical) ascending limb. Such were the curves obtained in our earlier work.[2] The arm was bared of clothing and raised in such a manner as to prevent constriction of the vein. In addition, pressure for hemostasis over the site of puncture was avoided; raising of the arm was sufficient to bring about control of bleeding. The observance of these precautions is of the utmost importance, for any interference with the free flow of blood between the site of injection and the entrance into the heart will materially influence the tracing and significantly reduce its diagnostic value. A two syringe technic was also developed to flush the sodium into the heart, but this again complicated the setup and was therefore discarded. It is of great importance to insure a good venipuncture and rapid injection. By observing these principles, we have obtained uniformly characteristic curves of the following description. It is likely that, with further improvements in the technic, better radiocardiographs will be obtained.

The precordial tracings in normal subjects consist of two principal waves connected by a plateau-like transitional point (fig. 2). The tracing reads from right to left; the injection point is at the far right. For purposes of simplicity the first wave has been called the R wave; it traces the blood through the chambers of the right side of the heart. The second wave, which traces the blood through the large pulmonary veins behind the heart, and the left cardiac chambers, is termed the L wave.

The R wave has the following characteristics: the upstroke, which represents the arrival of the sodium 24 into the superior vena cava and the right cardiac chambers, rises abruptly one-quarter second to two seconds after the injection. Sometimes, after it reaches a peak and describes a sharp point, it immediately descends. In other instances, there is a short

Dr. John Lawrence, Dr. R. W. Dunn and other members of the staff at the University of California in Berkeley supplied sodium 24; Dr. Lewis Bullock and Dr. John D. Little provided patients with congenital heart disease, and Miss Joan Oppenheim, Mrs. Sylvia Deutsch, Mrs. Lee Panish and Mr. Sol. Greater gave technical aid in the experiments. Dr. I. C. Brill assisted in the preparation of the manuscript.

1. The apparatus was designed by Dr. Burton F. Miller of Los Angeles.

2. Prinzmetal, M.; Corday, E.; Bergman, H. C.; Schwartz, L. L., and Spritzler, R. J.: Radiocardiography: A New Method for Studying the Blood Flow Through the Chambers of the Heart in Human Beings, Science **108:** 340 (Sept. 24) 1948.

plateau at the top of the wave. The wave descends because the labeled blood is leaving the right side of the heart. The descending limb of the R wave is vertical at first, but soon slopes gently into a J-shaped curve; the bottom of the "J" is called the transition point or zone. When the R wave is plotted on semilogarithmic paper, it resembles the dye concentration curves of arterial blood utilized for the determination of cardiac output.[3] On semilogarithmic paper the descending limb of the R wave forms a straight line. The transition point corresponds to the time when most of the labeled blood is in the lung on its way from the right to the left side of the heart.

The L wave is much lower than the R wave, but is about twice the duration of the latter. The lower amplitude as well as the longer duration of the left-sided complex is explained by the fact that the sodium 24 is diluted in a larger volume of blood as it flows through the vast pulmonary vascular bed into the pulmonary veins and left cardiac chambers. The ascending limb of the L wave, which represents the filling of the great veins and the left side of the heart, is of short duration—one to three seconds; it is followed by a long gentle slope of descent, representing the emptying of the left cardiac chambers of the bulk of labeled blood. The wave finally reaches an equilibrium above the baseline and continues in a horizontal line. The descending limb of the L wave is the longest portion of the tracing. Its duration in normal radiocardiograms may be as long as the sum of the entire R wave plus the ascending limb of the L wave.

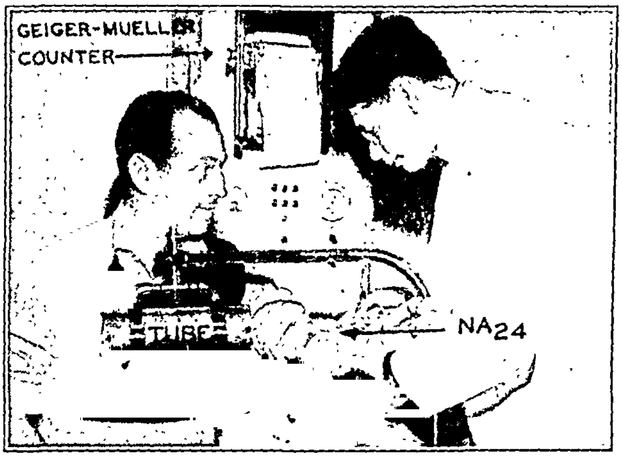

Fig. 1.—Demonstration of the technic of radiocardiography. The shielded Geiger counter tube is in front of the precordium. The Geiger counter is shown in the background. The radioactive sodium ($Na^{24}$) is injected into the antecubital vein.

## CLINICAL APPLICATIONS

During the past two years we have found the procedure to be of clinical value in the diganosis and prognosis of several cardiac conditions. It proved especially useful in differentiating heart disease from other conditions which tend to simulate myocardial insufficiency—a differential diagnosis sometimes difficult or impossible to establish by other methods. Furthermore, on several occasions, by this method, heart disease was discovered in persons in whom such disease was never suspected.

The following observations illustrate the usefulness of this new procedure in clinical diagnosis and prognosis:

1. Figure 3 shows a radiocardiogram of a 56 year old man who had emphysema and decided pulmonary fibrosis. For the previous seven months he had pronounced edema of the ankles. He was seen by a competent cardiologist who diagnosed the condition as heart failure, for which digitalis and diuretics were prescribed. There was no improvement. The radiocardiogram showed that the pumping qualities of the heart were normal; the subsequent course revealed that the ankle edema was due to lymphatic obstruction.

2. Figure 4 is that of a 73 year old man who was sent up from the surgical wards as a normal control without heart disease. The radiocardiogram was grossly distorted; it exhibited a long monophasic wave with decided prolongation of the descending limb. It was obvious that the curve was abnormal. The patient was therefore studied more closely, and although results of physical examination were normal, roentgen studies revealed a tumor mass pressing on the auricles and the posterior mediastinal structures.

3. Figure 5 is the tracing of a woman sent for radiocardiographic study as a normal control and presumed to be without heart disease. Her blood pressure and results of physical examination of the heart were normal. The radiocardiogram revealed a prominent L wave. A diagnosis was made of enlargement of the left side of the heart. Roentgen studies revealed an increased transverse diameter of the heart. Further investigation into her history disclosed that she had had hypertension in the past.

4. In the dyspnea of pulmonary insufficiency resulting from such conditions as emphysema, it is often difficult to determine to what extent, if any, associated heart disease is responsible for the clinical picture. In such instances a radiocardiogram is of great aid in revealing the presence or absence of abnormal cardiac dynamics. The employment of the circulation times for this purpose is subject to grave errors.[4]

5. In isolated dilatation of the left side of the heart, with or without dilated pulmonary veins, the L wave is widened and the descending limb is prolonged. The R wave is normal. We have repeatedly seen this pattern in aortic insufficiency and in hypertension (fig. 6).

6. In pure right-sided dilatation, the right ventricle will necessarily discharge the labeled blood slowly into the lungs and the flow to the left side of the heart would be correspondingly prolonged, even though the latter chambers are free of disease. Therefore, the observation of a low wide L wave in the presence of a wide R wave does not necessarily prove that the left chambers are also involved in the disease process. The radiocardiogram of a patient with severe emphysema is shown in figure 7. If both the right and left chambers are dilated, the prolongation of the left complex is greatly accentuated.

7. If the heart appears enlarged on the roentgenogram or physical examination, it may be possible to tell by this method whether or not the heart is merely concentrically hypertrophied or whether the chambers are excessively dilated and do not empty properly. In the former instance the curves have a normal configuration, whereas in the latter there is always decided distortion of the radiocardiogram; there is usually widening of the R or L wave with decided prolongation of the descending limb of the L wave. Thus, in 2 similar cases, although the caridothoracic ratio

[4] Corday, E., and Prinzmetal, M.: Unpublished observations.

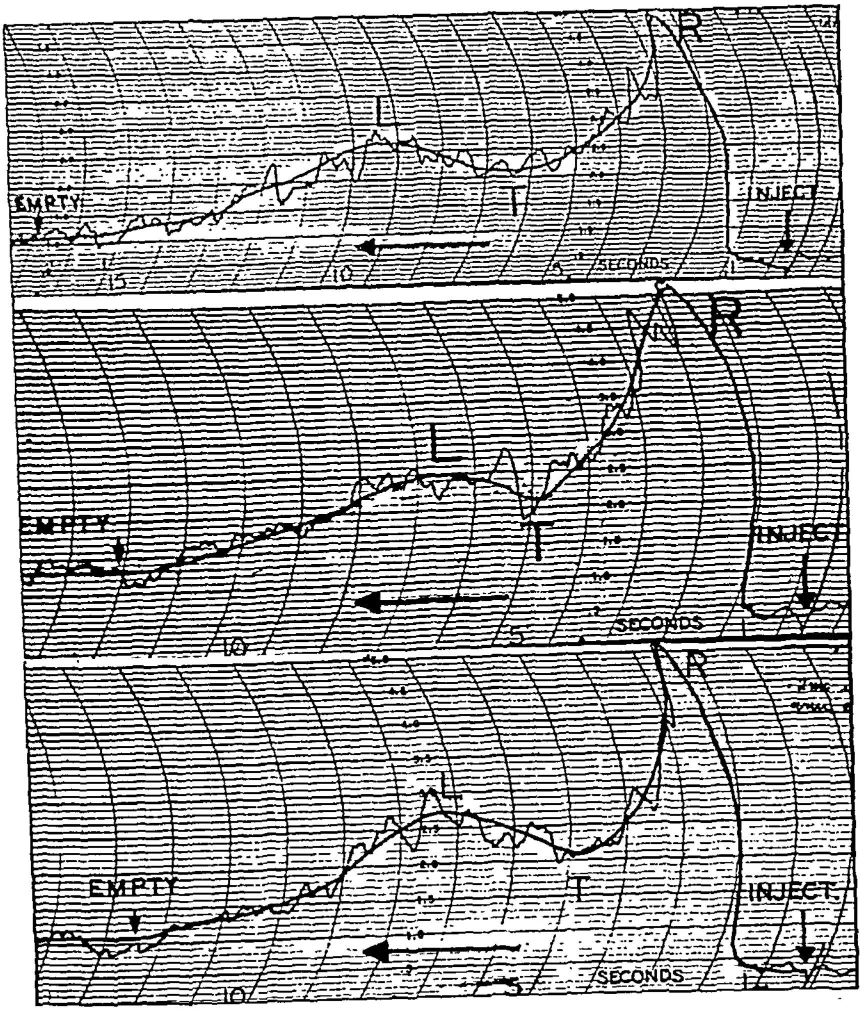

Fig. 2.—Radiocardiograms of 3 normal patients. All tracings read from right to left. Vertical lines are at one second intervals. The well defined R and L waves and *the transition point* (T) may be noted. The R wave represents blood going in and leaving the right side of the heart. The L wave represents blood going in and leaving the left side of the heart. The transition zone is the point where most of the blood is in the lungs.

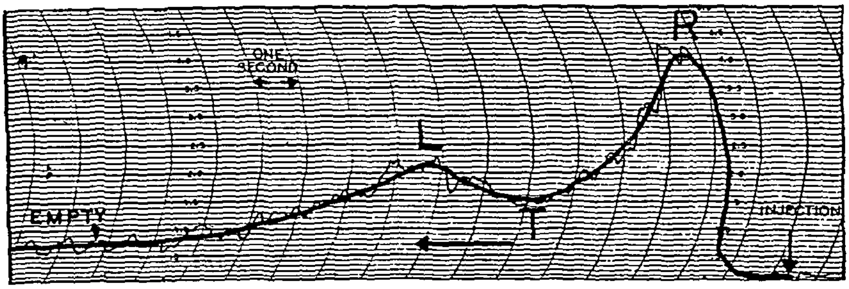

Fig. 3.—Radiocardiogram of P. M., a patient with emphysema, pulmonary fibrosis and severe edema of both lower extremities, which was diagnosed as heart failure. The radiocardiogram is normal. Subsequent examination revealed a normal heart and that lymphatic obstruction was the cause of the ankle edema.

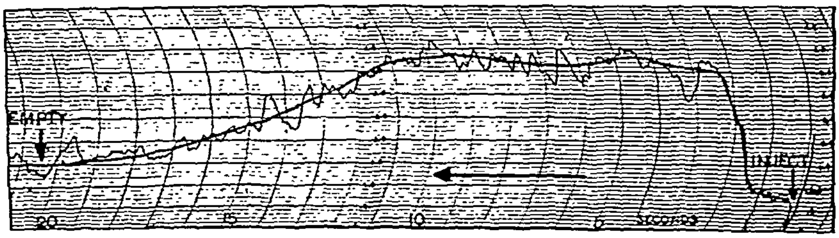

Fig. ' [illegible] ., a patient se[illegible] as normal co[illegible] of the radiocardiogram was seen, with fusion of R and L waves and prolongation of the L wave. Results of physical examination of the heart were negative. Lateral oblique roentgenograms revealed a large mediastinal tumor pressing on the posterior aspect of the heart.

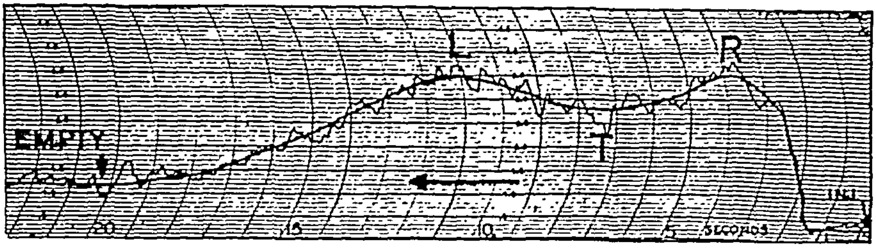

Fig. 5.—Radiocardiogram of L. C., a patient in whom no heart disease was suspected. Great prolongation of the L wave may be noted. Subsequent roentgen examination revealed enlargement of the heart, predominantly of the left ventricle.

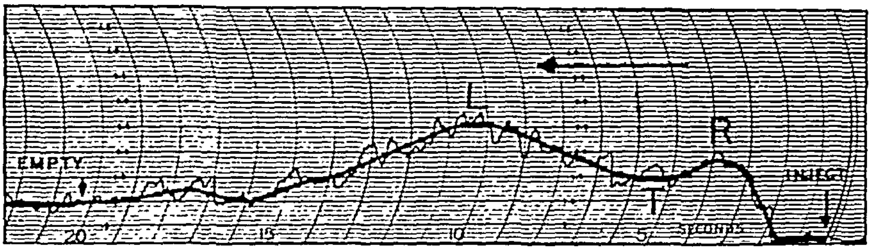

Fig. 6.—Radiocardiogram of I. G., a patient with aortic insufficiency and rheumatic heart disease. The L wave is of higher amplitude than the R wave and of abnormally long duration. This is characteristic of enlargement of the chambers of the left side of the heart. There is no evidence of failure.

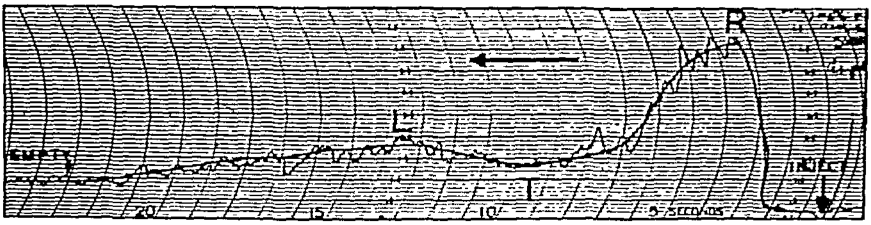

Fig. 7.—Radiocardiogram of M. S., a patient with pulmonary insufficiency, with severe emphysema and decidedly decreased vital capacity but no evidence of heart failure. The roentgenogram showed an enlarged heart. The bulk of the labeled sodium enters the right side of the heart rapidly, indicating that there is no obstruction between the site of injection and the right side of the heart; the descending limb of the R wave, however, is very oblique and of long duration, because the right side of the heart empties the labeled blood inefficiently. The L wave is shallow.

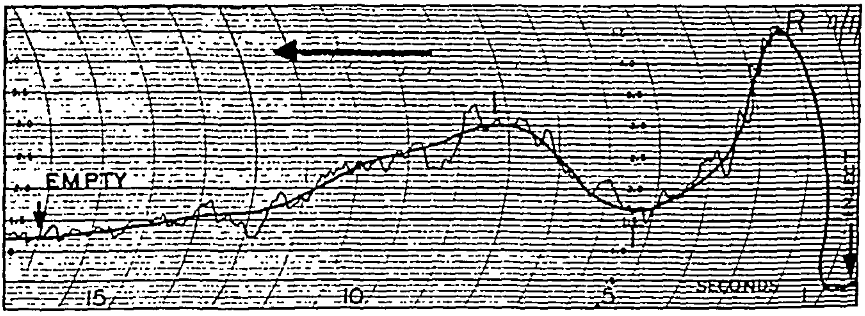

Fig. 8.—Radiocardiogram of I. S., a patient with rheumatic heart disease with aortic and mitral valvulitis, with no evidence of heart failure. The roentgenogram revealed left and right ventricular enlargement. There are a normal R wave, distinct transition point and a normal L wave, with good definition of each, denoting normal hemodynamics. Enlargement of the heart roentgenologically in the presence of normal hemodynamics is interpreted as concentric hypertrophy of the heart without dilatation.

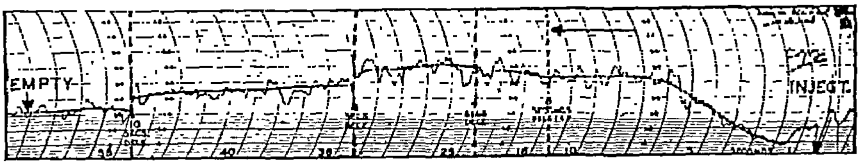

Fig. 9.—Radiocardiogram of A. F., a patient with congestive heart failure, arteriosclerotic heart disease and old myocardial infarction. The roentgenogram revealed bilateral pleural effusion and enlargement of both cardiac chambers. Slow filling of the right side of the heart, fusion of the R and L waves and the remarkable slow emptying of the left side of the heart may be noted.

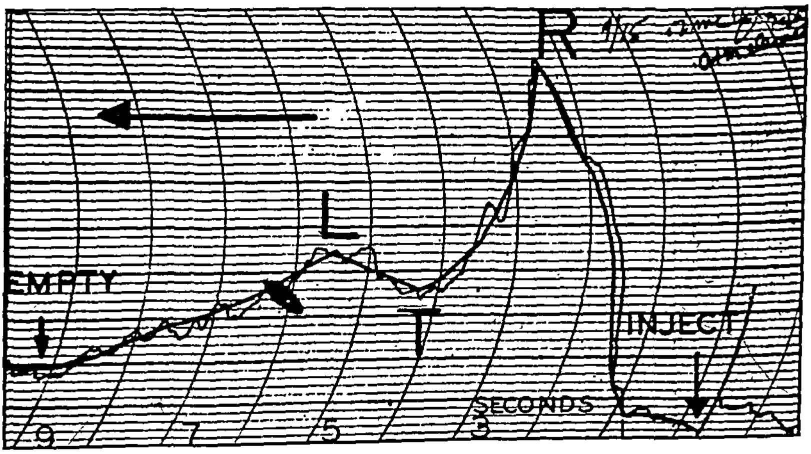

Fig. 10 (J. S.).—A case of thyrotoxicosis. All phases of the tracing are short.

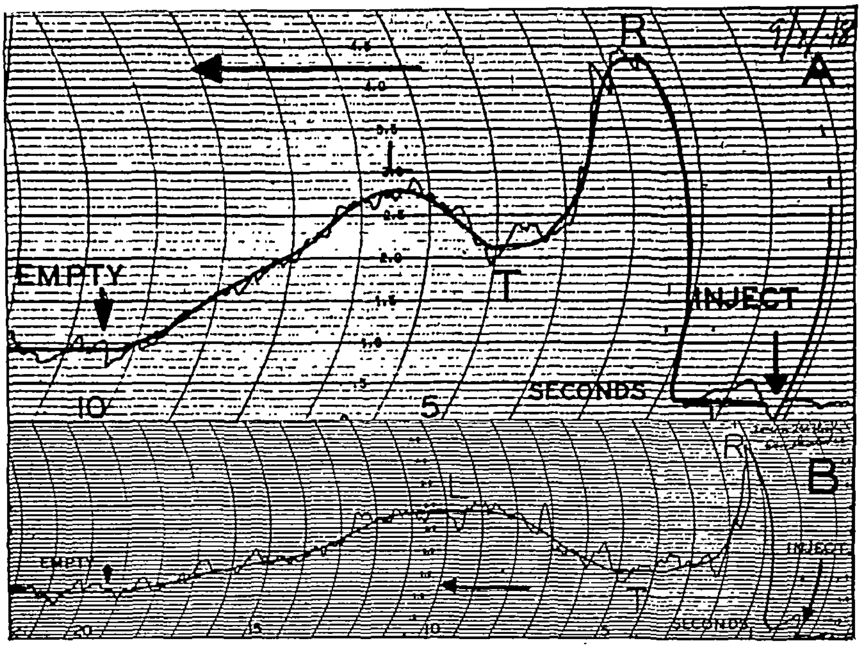

Fig. 11.—*A*, radiocardiogram of L. L., a patient with healed myocardial infarction; there is no evidence of heart failure; the radiocardiogram is normal. R and L waves are well defined and of normal duration, showing normal hemodynamics. The roentgenogram showed a normal-sized heart. *B*, radiocardiogram of A. E., a patient with recent myocardial infarction with recovery from congestive failure. At the time of reporting the patient showed no evidence of failure. The roentgenogram showed pronounced enlargement of the left side of the heart. Normal hemodynamics of the right side of the heart may be noted, but a greatly prolonged L wave, denoting a decidedly dilated left side of the heart.

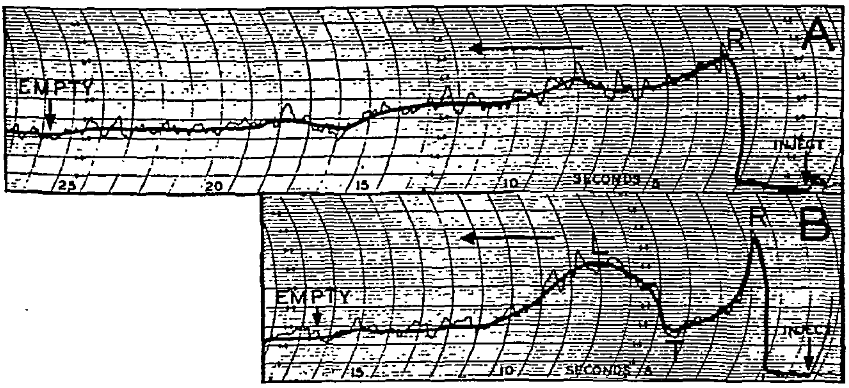

Fig. 12.—*A*, radiocardiogram of L. G., a patient with patent ductus arteriosus before surgical treatment. The R wave fuses into a greatly prolonged ill defined L wave. The L wave is prolonged because of shunting of blood from the left to the right side of the heart and recirculation. *B*, radiocardiogram of the same patient after operation, showing the well defined R wave, L wave and transition point previously not discernible. The L wave is *dome-shaped* and *slightly* prolonged, indicating some enlargement of the left side of the heart.

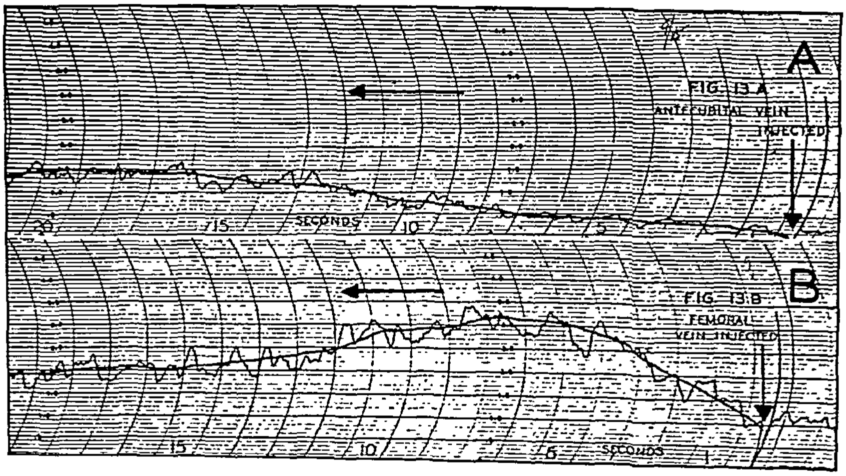

Fig. 13.—*A*, radiocardiogram of E. J., a patient with superior vena caval obstruction. Injection was made into the antecubital vein. The delayed and ill defined R wave denoted blocking of venous return. *B*, radiocardiogram of the same patient. Injection was made into the femoral vein. After injection the bulk of the labeled sodium enters the right side of the heart much more rapidly than after injection into the antecubital vein.

might be equally enlarged, observation of a normal radiocardiogram in one would indicate for that patient concentric hypertrophy (fig. 8) and hence a better prognosis than for the other patient, whose heart is no larger but whose radiocardiogram is abnormal.

8. In 2 patients with funnel chests, who exhibited no subjective symptoms, but whose hearts appeared distorted by both physical and roentgen examinations, we obtained normal radiocardiographic tracings. Thus, the revealed normal hemodynamics were in keeping with the absence of clinical symptoms.

9. We observed very early in the course of our examinations that patients with congestive heart failure had very wide radiocardiographic tracings, always with a decided prolongation of the L wave and generally with complete or incomplete fusing of the R and L waves (fig. 9). This subject will be discussed in other publications.

10. Radiocardiograms of adults with thyrotoxicosis and of infants and young children show that the sodium circulates through the chambers of the heart more rapidly than in normal adults (fig. 10).

11. Patients with old coronary artery disease with good cardiac function may have normal radiocardiograms (fig. 11 *A*), but when the heart begins to dilate there always develops a prolongation of the L wave (fig. 11 *B*).

12. Our observations on congenital heart disease have been very few; the usefulness of the radiocardiogram in this type of heart disease is yet to be proved. However, preliminary observations, in 2 cases, seem to indicate that in the tetralogy of Fallot the R wave appears normal but the L wave is absent or very shallow.

13. In cases with left to right shunt, the L wave appears to be abnormally enlarged. Figure 12 *A* is a radiocardiogram of a boy with patent ductus arteriosus. There is decided fusion of the R and L waves. After surgical closure the R wave became normal; there was good definition between the R and L waves and a well defined transition point appeared (fig. 12 *B*). The L wave, however, was dome-shaped and very prominent, suggesting that dilatation of the left side of the heart still persisted. This indicates that in such cases it takes some time for the enlargement of the heart to return to normal after surgical treatment.

14. This method is of value in the diagnosis of vena caval obstruction, superior or inferior. For this purpose comparative tracings were obtained after injections into the femoral and antecubital veins, respectively. By use of this technic in a case of obstruction of the superior vena cava it was found that the femoral vein injection gave a prompt rise of the R wave two seconds after injection, whereas after the antecubital injection it took about five seconds before the R wave began to appear, and its ascent was very gradual. This was interpreted as revealing a block in the superior vena cava (fig. 13).

## SUMMARY AND CONCLUSION

Radiocardiography offers a simple and safe method for the determination of the pumping qualities of the heart. The method is still in the experimental stage, but it has already yielded valuable information in the diagnosis of certain types of heart disease.

## ABSTRACT OF DISCUSSION

Dr. Gustav Nylin, Stockholm, Sweden: I admire this dynamic evolution using radioactive substances in studies of the circulation that Dr. Prinzmetal and his co-workers have done. It opens new possibilities for study. It is astonishing to see that it was possible to study the filling and emptying of both cavities separately. No one has done that before. Dr. Prinzmetal and his co-workers have given ideas and solutions to problems that I cannot grasp. I should like to give attention to that interesting phenomenon that they have shown, which they found typical in dilatation of the left ventricle. It takes rather a long time to empty the left ventricle in some conditions, and that is why I started my studies six years ago in labeling blood, because I tried to find out whether the substance was physiologic and connected with the blood elements. Then I confirmed my idea that the amount of blood in the heart played a great role. Somebody has said that my results were not right. However, Dr. Prinzmetal and his co-workers have confirmed my results, that there must be residual blood in the left ventricle so that the left ventricle does not completely empty during systole. The receivable blood plays a very important role in the mixing, and the work of Dr. Prinzmetal and his co-workers is very practical when used for studying pathologic cases, especially in congenital heart disease.

Dr. Willard D. Mayer, Detroit: How long do the patients manifest this radioactive activity? How long afterward will the Geiger counter show evidence of this isotope being in the system? Have there been over any period of time any harmful effects at all that have been noted with the use of this particular isotope?

Dr. Louis J. Vorhaus, Chicago: First, I am interested in knowing whether any studies have been done in high output types of failure. Second, I wonder whether Dr. Prinzmetal and his co-workers have done any studies on patients in congested failure, before and after treatment with digitalis.

Dr. Gustav Nylin, Stockholm, Sweden: I am happy to hear the question as to the danger in the use of the radioactive substances. We in Sweden have been very much interested in this question. We use 0.003 millicurie of radioactive phosphate. It is an extremely small amount. We are sure that such a small quantity should not be dangerous to use. We have followed our patients for weeks, and we have been able, a week after our observation, to find radioactive material.

Dr. Myron Prinzmetal, Los Angeles: Before starting this work, we consulted several experts in the field of atomic energy in California and elsewhere. Their opinion was unanimous that the amount of radioactivity we use is completely safe by all methods of estimation. Some investigators have used larger amounts without apparent harm. Twenty-four hours after injection, the patient has very little radioactive sodium, since sodium is rapidly excreted by the kidneys and has such a short half-life. This we determined by doing random counts over the body. In the near future we intend using more sensitive apparatus. This should allow us to perform this procedure with even less sodium 24. We have not as yet performed any studies on patients with high output types of failure, although we have studied many patients with emphysema. In the near future we hope to study the immediate effect of intravenously administered digitalis preparations on patients with congestive failure.

---

**Names of Operations for Hernia.**—It is difficult enough for medical students and residents to understand the basic principles of the subject under discussion without being confused by the many terms applied to the same condition. It is my contention that in practically every branch of medicine and surgery too many proper names have been applied to certain diseases or operations. . . . The greatest confusion arises in discussing the types of operation used to repair hernias. Thus, we hear the names of Bassini, Halstead, Willys Andrews, Ferguson, Gallie, Wangenstein, MacArthur, Hotchkiss, Moskowitz, Blake, Mayo and many others applied to various procedures used to correct the condition.—Roland L. Maier, M.D., A Plea for Simpler Surgical Terminology, *The American Journal of Surgery*, January 1949.

# POSSIBLE HAZARDS OF HIGH FAT DIETS IN CORONARY DISEASE

MILTON PLOTZ, M.D.
Brooklyn

It is the purpose of this paper to emphasize one of the problems confronting gastroenterologists in the management of the patient with coronary disease. There does not seem to be any special predilection for the development of peptic ulcer in persons with coronary disease, although some workers have stated the belief that there is.[1] In any case, since both diseases are common in men in the middle decades of life, it is not remarkable that cardiologists and gastroenterologists should be called on fairly frequently to treat patients having both conditions.

The main body of this paper is to be devoted to some hazards in the management of the patient with ulcer with the dietary regimen commonly employed in this country, a diet which contains large amounts of fat and cholesterol. I do not wish to be too dogmatic about the presentation of a subject which is still controversial, namely, the role of cholesterol in the pathogenesis of coronary disease. Indeed, it is not necessary to present this theory in detail. I shall present protocols with some tentative suggestions and allow the future to take care of definitive judgment and detailed explanation.

## CORONARY SCLEROSIS AND ARTERIOSCLEROSIS

Coronary sclerosis is somewhat *different from* arteriosclerosis of the vessels of the extremities which one commonly thinks of in connection with the term "hardening of the arteries." In the extremities it is a lesion involving mostly the media with very little thickening of the intima, especially in the early stages. On the contrary, coronary sclerosis starts as a thickening of the intimal layer, and throughout its course, even in its most advanced stages, nearly all of the disease is localized in the intima with involvement of the media as a late and comparatively unimportant process. The pathologic process then is an atheroma, and the disease is best referred to as atheromatosis rather than arteriosclerosis. One other point deserves attention: coronary atheromatosis is the only important disease of the coronary arteries; other lesions comprise less than 10 per cent of all cases and are clinical curiosities. In other words, if the patient has any disease involving the coronary arteries—angina pectoris, coronary thrombosis or myocardial infarction—one can be reasonably certain that one or more of his coronary arteries has atheroma.

## CORONARY ATHEROMATOSIS AND CHOLESTEROL METABOLISM

There is considerable evidence that there is some sort of connection between coronary atheromatosis and cholesterol metabolism. In the first place, the atheroma, especially in its early stages, consists almost entirely of cholesterol. Secondly, it is a matter of common clinical observation that in those conditions in which the level of blood cholesterol is elevated, the incidence of coronary atheromatosis is much higher. Such conditions are myxedema, diabetes, familial xanthomatosis and lipid nephrosis. A number of workers have reported, too, that even among patients with coronary disease who do not have any of these other diseases the blood cholesterol is elevated above normal.[2] It may be taken as fairly definite, therefore, that there is some sort of link between cholesterol and atheroma. What is not definitely established is whether the lipid content of the diet has anything to do with the deposition of cholesterol in the intima.

## OBSERVATIONS

The first group consists of 10 patients, all of whom died. Of these, 9 had peptic ulcer. In all cases the story was startlingly similar. All of the patients were male. The age range was between 38 and 55. In each case, the patient was known to have definite coronary artery disease, as shown by a history of typical angina pectoris, electrocardiographic changes or, as in 3 cases, a previous myocardial infarction. In each case, the patient died within seven months after being placed on a high fat diet. In 1 case, the patient had been put on such a diet to "build him up" after a severe infection of the respiratory tract. In the other 9, duodenal ulcer had developed and the patient had been placed on an ulcer diet which was very liberal in the use of dairy fat.

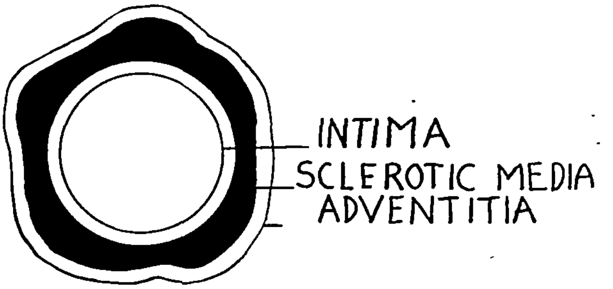

Fig. 1.—Medial sclerosis, a form of arteriosclerosis commonly found in arteries of the extremities but not in the coronary arteries.

A typical case was that of a machinist of 39 who had had typical angina pectoris for four years. He had had moderate hypertension and electrocardiographic changes consisting of an isoelectric T wave in lead 1. His attacks were not severe and were brought on by climbing two flights of stairs, walking briskly in the cold or by coitus. The seizures were not increasing in severity and did not interfere with his work in any way. The patient had typical symptoms of duodenal ulcer with hunger pain, most pronounced at night. The roentgenogram showed deformity of the duodenal cap and a questionable niche. The patient was then put on the type of ulcer diet commonly employed on the service of the hospitals with which I am associated and similar to that in use throughout this country, emphasizing especially the frequent ingestion of milk and cream. Although the hunger pains disappeared rapidly, within three weeks his anginal pain increased in frequency and intensity. Two months later the patient was suddenly seized with severe crushing pain in the chest and died in a telephone booth while calling for a doctor. Postmortem examination showed extensive atheromatosis of the left anterior descending coronary artery with thrombosis 1.5 cm. from the orifice.[3]

[3] Plotz, M.: Management of Combined Coronary Disease and Peptic Ulcer, Rev. Gastroenterol., **15**: 628 (August) 1948.

Another case was that of a furrier, aged 45, who had had typical angina pectoris for three years. His blood pressure was moderately elevated, 150 systolic and 100 diastolic. He had moderate squeezing pain substernally which radiated to the left arm on exertion or on exposure to cold. These attacks were mild, easily controlled by glyceryl trinitrate and did not interfere with his carrying on his affairs. The electrocardiogram showed evidence of myocardial damage in the form of intraventricular block. At the age of 45 the typical hunger pain of peptic ulcer developed, and roentgen investigation showed definite duodenal ulcer. This man was then put on a typical Sippy regimen with the frequent use of milk and cream. On this diet he quickly lost his symptoms of ulcer. Two months after he had started this diet, the angina pectoris grew gradually worse, and three months later the patient died. Postmortem examination showed atheromatosis of the left anterior descending coronary artery with thrombosis 1 cm. from the orifice.

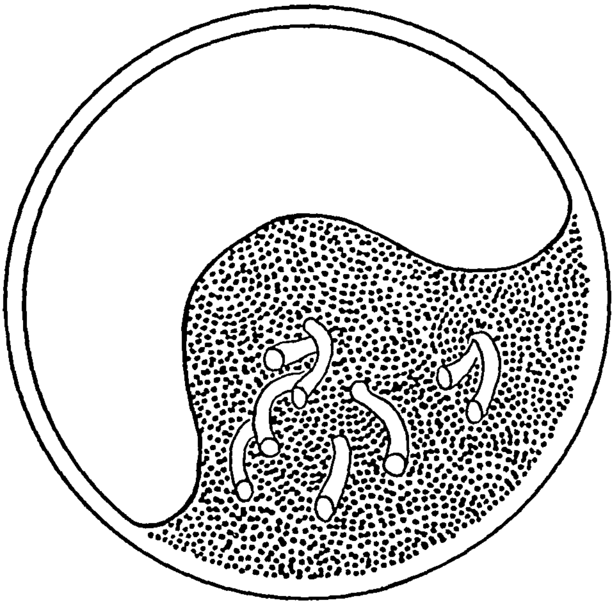

Fig. 2.—Atheroma of the intima, the lesion usually seen in coronary artery sclerosis.

A third case was that of a manufacturer of 52 who had had an anterior myocardial infarction at the age of 49. Following this episode, he had no angina or other symptoms referable to his heart and was able to carry on his work without interruption. During the past winter an infection of the respiratory tract developed, consisting of coryza and a mild sore throat which lasted for three days. At this time the patient, who had always been thin and wiry, came under the observation of a physician who had not treated him previously. In an effort to increase the patient's weight, the physician put him on a high calory diet in which the extra calories were given almost entirely in the form of dairy fat. The patient was advised to take ¼ pound (113 Gm.) of butter a day together with 8 ounces (237 cc.) of cream. The patient gained 5 pounds (2 Kg.) in six weeks. At that time a fresh coronary occlusion and an infarction of the posterior wall of the heart developed, and the patient died two days later.

There were six postmortem examinations performed. In four, consent was not obtained. In all cases, there was atheromatosis of one or more of the main coronary arteries. In 4, there was fresh thrombus; in all 6, there was myocardial infarction. The blood cholesterol was determined in only 3 patients and was over 320 in 2.

The second group consisted of 17 patients with known coronary disease in whom symptoms of peptic ulcer developed one or more years after the cardiac diagnosis was definitely established. These were all patients who were found by a systematic study of files of patients with peptic ulcer. None of these patients has died. All had been put on typical ulcer diets with frequent high fat feedings. In 12 of the 17, the symptoms of angina pectoris became much worse within a period of one to three months after the ulcer diet was started. Myocardial infarction developed in 3 of these patients.

## COMMENT

Any one who has made a statistical study of coronary disease knows how difficult it is to get comparable series of cases as controls. It would be necessary to obtain patients of the same age, sex, blood pressure and changes in the blood vessels. As a rough comparison, 17 patients with known coronary disease who had been placed on special diets for impaired gallbladder function were selected. Three months after starting their new diets, 2 of these had a deterioration of their cardiac condition, 1 of them a fresh myocardial infarction. This is in contrast with the series previously cited in which 12 of 17 patients were worse within three months after starting ulcer diets.

I realize that both groups of patients, the 10 that died and the 12 whose symptoms were made worse after starting high fat diets, are small and that conclusions cannot be drawn. Study of a large number of such persons may change these statistics. Nevertheless, the results are striking enough to warrant further investigation and to serve as a warning that high fat diets may be harmful to patients with atheroma of the coronary arteries. At this point, emphasis should be placed on what this paper does not attempt to prove. First, it should be noted that all of the patients had previous coronary disease and, therefore, a definite, even if only localized, disturbance in cholesterol metabolism. What the effect of high fat diets on persons with normal arteries would be I still do not know. I feel that, as a matter of elementary precaution, it would be wise to avoid the conventional ulcer diet in patients who are likely candidates for coronary atheroma, namely, those with hypertension, diabetes, myxedema, xanthomatosis and hypercholesterolemia. Secondly, from the data presented, one is not justified in assuming that a low cholesterol or a low fat diet would help a patient with coronary disease. Perhaps it will. What I am trying to show is only that a high fat diet may be harmful in such cases.

On theoretical grounds, there is some evidence that the cholesterol content of the diet has something to do with the formation of coronary atheroma.[4] Among certain races, like the Chinese and the Okinawans, whose diet is low in cholesterol, coronary disease is rare. The incidence of coronary disease diminished in Germany after the last war when the dietary fat was low. There were fewer coronary deaths in the British Army than among American troops with their higher fat intake. Wilens[5] has pointed out that there is less coronary disease among alcoholic persons who have some intolerance to fats. Lesions resembling atheroma in human beings may be produced in certain animals constantly and in others only under special conditions by the feeding of high cholesterol diets. To these bits of evidence may be added the cases presented herein.

---

[4] Moreton, J. R.: Atherosclerosis and Alimentary Hyperlipemia, Science **106**: 190 (Aug. 29) 1947.

The evidence is far from complete, and the links in the chain are not all forged. Steiner[6] reported that he was unable to raise the blood cholesterol level in a small group of patients with coronary disease to whom he fed high cholesterol diets or to lower it in patients on low cholesterol diets. This evidence in turn, even if confirmed in a larger series, is not conclusive as far as the major thesis of this paper is concerned.

At this point, I should like to present another case to show that it may not be necessary to raise the blood level of cholesterol for a high lipid diet to be harmful. A man of 47 with both peptic ulcer and coronary disease came under my observation after the threshold of suspicion concerning the Sippy diet had become rather low. I constructed for him a diet similar to the one already in use, but containing negligible amounts of cholesterol. It had, however, about as much fat. Much to my chagrin, this man had a myocardial infarction two and a half months later. There was a similar occurrence in a man of 52.

These cases suggested the possibility that a diet high in fat and low in cholesterol might be just as harmful as one high in cholesterol. Moreton[7] advanced a hypothesis which may be of great importance. He presented evidence that high fat meals induce hyperlipemia, that the size of the lipid particles is comparable to that of particles known to produce arteriosclerosis experimentally, that the intima may take up these particles and "foam cells" may be found and that the triglycerides and fatty acids are more readily resorbed and removed than cholesterol, which remains as the "difficult-to-remove residue." "When this residue of inert and difficult-to-resorb cholesterol is thus trapped between the high-pressure blood column on one side and the internal elastic membrane on the other, it is withheld and prevented from being dispatched to the liver (and possibly other sites), where theoretically it could be relatively easily degraded or eliminated by cells that are specialized in such metabolic functions. Thus, the accumulation of lipids in the arterial intima seems to be a local, mechanical problem, and unrelated to general body balance or over-all metabolism of these substances." He advanced the theory that the cumulative effect of many fatty meals producing transient showers of large lipid particles in the plasma may be "the underlying cause of the intimal lipid deposition in human atherosclerosis," a theory which receives some support from the material presented here. Theoretically, too, even if there is no cholesterol in the meal, the lipid particles may carry with them cholesterol already in the blood stream or which is released in the bile used to digest these fats.

In any case, whether one accepts the "cholesterol theory" of the induction of atheroma or not, the evidence to date is such that one should proceed with caution in the prescription of high fat diets to patients with known coronary disease. To be more specific as far as gastroenterologists are concerned, another type of ulcer diet should be advised for such persons. It is my feeling, since frequent feeding seems to be the effective factor in the ulcer diet, that it be retained but that the diet be constructed so as to be low in fat content and especially low in cholesterol.

SUMMARY AND CONCLUSIONS

The role of high fat diets in the pathogenesis of coronary disease is discussed. Ten patients are presented in whom death followed within several months after starting a diet high in fat. All of these patients had previous coronary disease. In another series of 17 patients with coronary disease in whom peptic ulcer developed, the symptoms of coronary disease became worse within three months after a high fat diet was instituted.

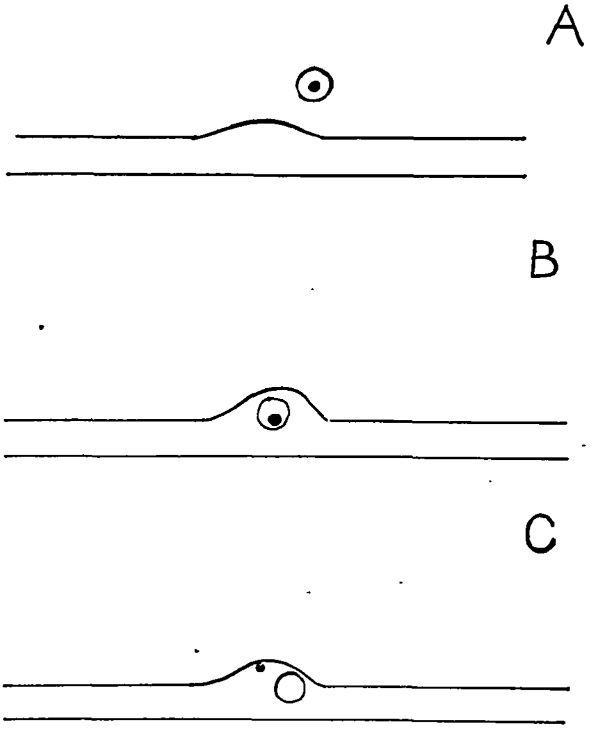

Fig. 3.—Highly schematic illustration of Moreton's hypothesis of the fate of lipid particles containing even small amounts of cholesterol. After the particle enters the intima (*B*), the neutral fats and fatty acids are removed, leaving the cholesterol (black dot) as the difficult to remove residue (*C*).

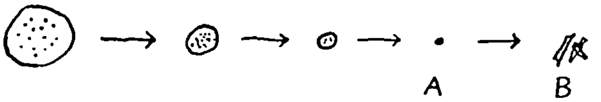

Fig. 4.—Moreton's hypothesis: Action of macrophages and tissue fluid enzymes on chylomicron, leaving cholesterol residue (*A*). Condensation of this residue from many chylomicrons to form cholesterol crystals (*B*).

There is no reason to believe that high fat diets injure persons with intact coronary arteries. The initial atheroma probably consists of endogenous cholesterol.

A high fat diet, even if low in cholesterol content, may be harmful. The possible mechanism is discussed. The use of a high fat diet in persons with coronary disease may be harmful. In such patients, an ulcer diet should consist of frequent feedings with low fat content.

## ABSTRACT OF DISCUSSION

**Dr. Louis N. Katz**, Chicago: For the past dozen years my associates and I have been devoting more and more of our energies to the problem of arteriosclerosis. My associate, Dr. Schlichter, has shown an inverse relationship between the ease of development of arteriosclerosis of the aorta in various species of animals and the vascularity of its walls. Thus in the chicken, in which aortic arteriosclerosis is readily produced, the vascularity is poor; in the dog, in which arteriosclerosis is difficult to produce, the vascularity is good. Other work done with the help of the late Dr. Dauber, Dr. Horlick and Dr. Stamler has left no doubt that in the chicken, which is omnivorous, high cholesterol feeding and high fat feeding will produce arteriosclerotic lesions similar to those occurring spontaneously in this species and in human beings. We have been able to show that the amount of arteriosclerosis is related to the quantity and the duration of the cholesterol feeding. It might therefore be argued that high cholesterol diets play a significant role in the production of arteriosclerosis. This seems to be substantiated by a study we have just completed on the effect of feeding a nearly fat-free diet to chickens which resulted in a reduction in the amount and frequency of arteriosclerosis. At first glance this would support the concept that dietary cholesterol is the important element in arteriosclerogenesis. But many chickens which received practically no exogenous cholesterol or lipid still showed some arteriosclerosis. True, the frequency and extent of arteriosclerosis was reduced, but, on the other hand, arteriosclerosis unquestionably developed in these chickens from endogenously produced cholesterol. Thus, it would seem that the prohibition of cholesterol or fat in the diet does not prevent the occurrence of experimental arteriosclerosis. From the evidence presented by Dr. Plotz, one must admit that 36 cases may not be a fair random sample. In fact, the problem of the relation of high fat diet to arteriosclerosis would have to be studied by a survey of several thousand cases adequately controlled and preferably carried out by a group of persons from different institutions before one could arrive at a clinical judgment. Dr. Plotz has raised an important question, but it seems to me that in the present state of knowledge one should not be deterred from using a high fat or high cholesterol diet, provided that there is an indication for its use. Furthermore, I cannot subscribe to the limitation of fat and cholesterol in the diet for the prevention or alleviation of arteriosclerosis except in limited cases, even though this prohibition has recently obtained ardent advocates. Finally, on the effect of a change in diet, it seems to me, on the basis of animal experiments, that it should take more than two to three months to produce arteriosclerosis in human beings.

**Dr. Walter L. Palmer**, Chicago: I agree with Dr. Katz that Dr. Plotz's conclusions do not seem justified by the evidence presented. After all, there are three common diseases; peptic ulcer, arteriosclerosis and hypertension. It is to be expected, therefore, that the coincidence of these three diseases will be great. I should like to ask Dr. Plotz whether he has measured the effect of low fat and high fat diets on the serum lipids. Some years ago, in dealing with a patient with xanthomatous biliary cirrhosis of the liver, and with an extremely high level of blood lipid, I set about with great enthusiasm to reduce these levels by means of an extremely low fat diet. The results of my efforts were disappointing. As a result of this, it seemed necessary for me to conclude, as Dr. Katz has indeed concluded, that the ability of the organism to synthesize lipids from nonlipid food is great and that there is therefore much more to this problem than lowering the fat intake.

**Dr. Milton Plotz**, Brooklyn: Strangely enough, I do not find myself in complete disagreement with Dr. Katz. I should like to point out that in a sense my patients had already performed a cholesterol tolerance test on themselves with positive results; in other words, I started out with patients who were known to have coronary disease. I was not starting out with chickens, as Dr. Katz did, that presumably had normal arteries. As I said before, I have not the slightest idea of what the effect would be of feeding a high fat diet to a patient who had normal coronary arteries. However, my patients did not fall in that category. They were patients who already had known atheroma and had already demonstrated the fact that they could not synthesize normally either endogenous or exogenous cholesterol. Dr. Katz put his finger on the central part of this problem, which Dr. Palmer did not answer, and that is: Are high fat treatments necessary in peptic ulcer? In talking with different gastroenterologists I have been led to believe that it is the frequent feeding that is important and that it is not necessary to add large amounts of fat to the ulcer diet.

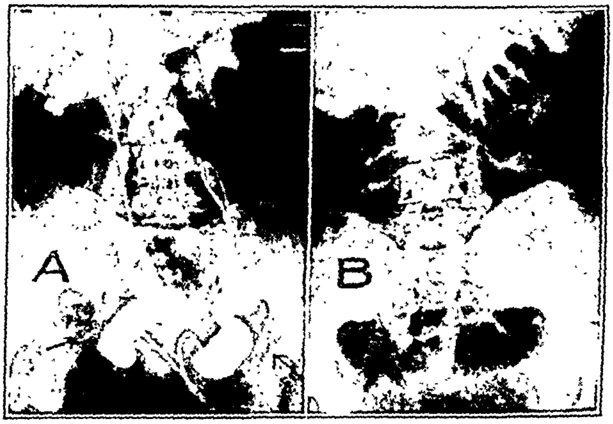
# MANAGEMENT OF PATIENTS UNDERGOING URETEROINTESTINAL ANASTOMOSIS

## Preoperative, Operative and Postoperative Measures

R. H. FLOCKS, M.D.
Iowa City

Safe ureterointestinal anastomosis widens the scope of treatment of certain congenital anomalies of the bladder and urethra and also makes possible more adequate treatment (radical or palliative) of three common types of carcinoma: carcinoma of the urinary bladder, of the prostate and of the female genital organs. Several recent developments have so greatly increased the safety of this operation that, in a recent series of 35 patients over 40 years of age with carcinoma in the aforementioned locations, only 1 death occurred and the only complication associated with the operative procedure was infection of the urinary tract, which occurred in only 6 per cent of the patients and was easily controlled with antibiotics. Also it was possible to perform ureterointestinal anastomosis safely on decidedly dilated ureters (figure). These developments include: (1) great improvement in the maintenance of nutrition in the preoperative and postoperative periods, (2) the use of the newer antibiotics and (3) the recognition of the role of maintenance of the blood supply in the wall of the bowel and ureter in the determination of the fate of the region of the anastomosis. This paper gives in detail the preoperative, operative and postoperative measures used to preserve adequate general nutrition, to control infection in the bowel and urinary tract and to prevent ischemic necrosis in the region of the anastomosis.



Case of extrophy of the bladder with pronounced bilateral hydroureter transplanted successfully by the method described. *A*, before operation. *B*, intravenous pyelogram after operation. (Permission of Dr. Oscar Carter.)

Professor, Department of Urology, University Hospitals, College of Medicine, State University of Iowa, Iowa City.

Read before the Section on Urology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

### PREOPERATIVE MANAGEMENT

The management prior to ureterointestinal anastomosis takes from four days to several weeks, and its purpose is threefold: (1) to promote the general nutrition of the patient, (2) to prepare the bowel for the procedure and (3) to eliminate infection of the urinary tract, if possible.

The promotion and maintenance of general nutrition are extremely important, since many of the patients are in the upper age groups and have the secondary anemia and hypoproteinemia associated with their age and disease. These conditions interfere with healing at the point of anastomosis, which in turn leads to leakage and peritonitis or scarring which later causes hydronephrosis and pyelonephritis. The measures which have been used in this series of 35 patients include: (1) correction of the anemia and hypoproteinemia by the use of blood transfusions, (2) infusions of blood plasma and (3) a low residue–high protein liquid diet. The diet is supplemented by multivitamin capsules, 1 capsule four times daily, and vitamin K (menadione sodium bisulfite [hykinone®]), 4.8 mg. intramuscularly twice daily. The latter is used in order to counteract the destruction of the organisms in the bowel by the succinylsulfathiazole, since the organisms are supposed to synthesize vitamin K. Vitamin C, 200 mg. three times a day, is also given. A daily fluid intake of approximately 3,000 cc. is maintained. With this regimen the nutrition can be raised to an adequate level and maintained at such a level.

For four days prior to the operation, measures are instituted to obtain as clean a lower bowel as possible. On the first of the four days the patient is given 30 cc. of castor oil and placed on a low residue diet. Soapsuds enemas are given until the eliminated fluid is clear. On the following three days the low residue diet is continued and enemas, as aforementioned, are repeated each day. At the same time 1 Gm. of succinylsulfathiazole is given four times daily. Streptomycin, 0.5 Gm. in milk, is given four times daily. It has been shown in our patients that succinylsulfathiazole definitely reduces the bacterial count of the stools. The addition of the streptomycin did not make much difference in the bacterial count of the stools. It has been added, however, on an empiric basis. The morning of the operation, the lower bowel is thoroughly irrigated with sodium chloride solution and a rectal tube is left in place. A Miller-Abbott tube is introduced the night before, and the tip is allowed to go into the jejunum; this makes possible the control of distention postoperatively and the immediate intake of fluid nutrition by mouth.

The infection of the urinary tract is best controlled by the administration of 100,000 units of penicillin intramuscularly every three hours and any local treatment that may be indicated in the individual patient.

### OPERATIVE MEASURES

There are many types of operation for creating a ureterointestinal anastomosis, but all, in order to be successful, must avoid damage and scarring of the ureterocolic junction by following certain principles. The blood supply within the bowel and ureter at the point of the anastomosis must be preserved. The accomplishment of this (in my opinion) is the most important reason for the greatly improved results which are being obtained. I have shown that a satisfactory way to preserve the ureteral blood supply is to maintain the ureters intact for ten to twelve days after the completion of the anastomosis, thus permitting the operative area to obtain blood from the ureteral arteries both above and below the region of the anastomosis.[1] Marshall[2] and Ferris[3] have emphasized the importance of eliminating compression of the ureter by avoiding tight sutures about it as well as the need for not stripping the ureter of its adventitia in order to maintain its blood supply. Marshall, Lowsley and others have stressed the need for maintaining the blood supply in the bowel wall and have made a bed in the sigmoid by the combination of sharp and blunt dissection in such a way that tearing across the blood vessels is minimal. Tension at the point of anastomosis has been prevented by bringing the bowel to the ureter and keeping it there by tacking it to the parietal peritoneum. The importance of this has been stressed by Jewett.[4] Infection at the point of the anastomosis is prevented by keeping the bowel as clean as possible and by avoiding contamination of the area by bowel contents. It is my opinion that this can be reduced to a minimum through the maintenance of adequate circulation at the point of anastomosis: if adequate circulation is not present infection cannot be prevented. Obstruction of the ureter is eliminated by avoiding compression with sutures and by the use of indwelling ureteral catheters or T tubes. Late obstruction is due to excessive scarring which results from ischemic necrosis with infection of the ureterocolic stoma. The adoption of measures to maintain circulation in the ureter and bowel, with the avoidance of infection, tension and obstruction to the outflow of urine, will produce a good result and avoid late obstruction.

### POSTOPERATIVE MANAGEMENT

It is important to maintain good nutrition postoperatively in order to obtain rapid healing. In this connection, it has not previously been emphasized that the use of the Miller-Abbott tube with its weighted tip in the jejunum is extremely valuable. Its advantages are twofold: first, in combination with a rectal tube it will control abdominal distention and thus prevent tension on the lines of suture and compression of the small vessels in the walls of the bowel and ureter at the operative site; second, it makes possible the use of a high protein nonresidue liquid diet within twenty-four hours after the operation. This diet can be given by mouth and for the most part will be absorbed in the stomach and duodenum and first part of the jejunum. The unabsorbed portions will wash back through the Miller-Abbott tube and thus cannot cause difficulty in the lower bowel. For the first twenty-four hours after the operation water is given by mouth as tolerated and is supplemented intravenously by 500 cc. of citrated blood, 600 cc. of dextrose and 800 cc. of isotonic sodium chloride solution. On the following day the high protein nonresidue liquid diet is started and is supplemented by 800 cc. of isotonic sodium chloride solution and 800 cc. of 5 per cent dextrose given intravenously. Multivitamin capsules are given by mouth, 1 capsule four times daily; 200 mg. of vitamin C are given three times daily, and vitamin K is given twice daily, as it was given preoperatively. On the third and fourth days the procedure is essentially the same. A rectal tube is inserted immediately after

not always obtained in full for all patients in this series, but in enough to warrant the importance of multiple points in evaluation; in all cases at least seven and in over half eight or nine were available. These will be taken up separately in more detail. In addition to these ten criteria, each patient was given at the onset of the investigation a neurologic and physical examination.

Table 1.—*Duration of Treatment with Parpanit®*

| Duration (Mo.) | No. of Patients |
|---|---|
| Over 12 | 1 |
| 9 to 12 | 10 |
| 6 to 9 | 9 |
| 3 to 6 | 22 |
| Under 3 (failures) | 8 |
| New patients not included in report | 17 |

## CRITERIA FOR JUDGING EFFECT OF TREATMENT

1. The subjective report of the patient: The patients were seen frequently during the first three months. On each visit a detailed report of how the patient felt, what percentage of improvement he would assign to himself over his previous medication and no medication and an account of the side effects or other subjective symptoms was taken.

2. The report of relatives: These were obtained on every visit on which a relative was present and included an estimate of the percentage of improvement. Many persons are unable to give their impressions in exact percentages, but could usually say whether the improvement was 10, 20, 30 or 50 per cent. The general mood and attitude of the patient toward his disease and toward other persons was picked up in this way, and it was usually clear in the cases in which there was improvement that this impression was shared equally by relatives and friends.

3. Appearance and posture: The appearance of the patient to the examining physicians in the investigation was noted at each visit. This was a general impression, of course, which was difficult to quantitate. Such items as vigor of the voice, appearance of the face, expression and mood, were included in this assessment. In addition, an effort was made to quantitate the amount of abnormal posture by dropping a plumb line from the external auditory meatus to the floor when the patient was standing in his usual position. In the patients who were overflexed as a result of their disease this plumb line would fall in front of their toes or in the region of their toes. Improvement in posture could be measured by the amount of displacement of the line toward the posterior part of the foot.

Table 2.—*Points Noted in Evaluating Results in a Case in Which Treatment was Successful and a Case of Failure* *

| | Points Evaluated | Case of Success | Case of Failure |
|---|---|---|---|
| 1 | Subjective report of patient | + | 0 |
| 2 | Report of relative | + | 0 |
| 3 | Appearance and posture | + | 0 |
| 4 | Performance in daily life | + | — |
| 5 | Neurologic examination | 0 | 0 |
| 6 | Electromyogram | + | — |
| 7 | Movement rate and gait | + | 0 |
| 8 | Handwriting | 0 | 0 |
| 9 | Placebo and substitution effect | + | 0 |
| 10 | Opinion outside medical observer | + | 0 |
| | | 8 | —2 |

* The pluses show clearly in the successful case, and the failure is equally definite; +, better; 0, no change, and —, worse.

4. Performance and daily life: Both patients and relatives reported on this. They included such data as the patient's ability to shave, feed and dress himself and changes as a result of medication in these tasks. Data about hobbies, exercise, walking, stair climbing, working and sleeping were all recorded in each case. For example, a patient might state that since receiving parpanit® he could get in and out of the bathtub himself, which was previously impossible, and this report might have to be compared with that of another patient who felt he could turn over in bed more easily than he could previously. Quantitation between patients was therefore most difficult, but the individual changes that were either favorable or unfavorable were usually clear.

5. Neurologic examination: This included passive swinging of the patient's arms from alternate rotation of the shoulders while the patient was standing, assessment by the examiner of the "feel" of resistance on passive motion of the joints, presence and amount of cogwheeling in each joint, amount of the tremor present and amount of resistance in head motion to passive movements.

6. Electromyograms: Electromyograms were done in all cases, and the technic was constant for all examinations. Four pairs of surface electrodes were placed over the muscles of the limb that was being examined, so that four separate muscles could be tested at the same time. The output from these four sets of electrodes was fed into a standard Grass electroencephalograph and the discharge recorded at a paper speed of 6 cm. per second. The output of one set of electrodes was, in addition, fed into an integrating voltmeter which had been previously calibrated so that the integrated voltage for a fixed period of time could be indicated on the electromyograph paper by clicks from a signal pen.

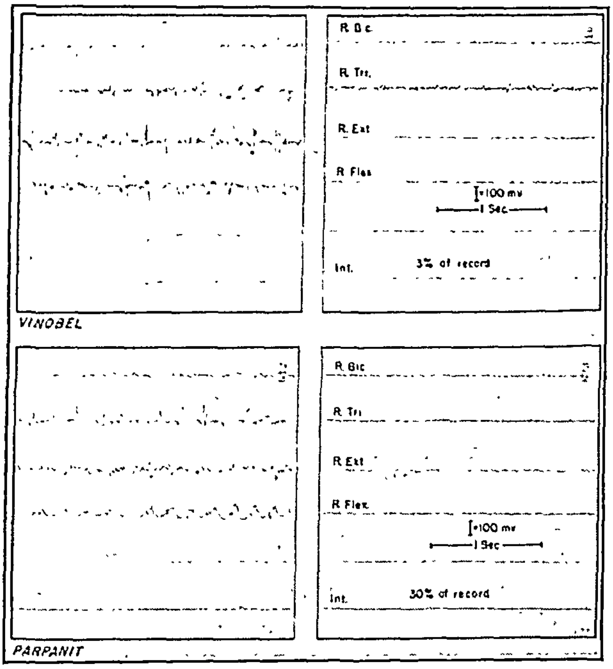

Fig. 2.—The electromyogram in a typical case (Dr. G. with postencephalitic parkinsonism) stabilized on vinobel® (contains alkaloids of belladonna root obtained by extraction with wine) compared with that stabilized on parpanit®. The upper left chart shows a sample of the worst part of a five minute run with the patient taking vinobel® and the right upper chart a sample of the record with the minimal resting activity. Minimal activity occurs in this case only 3 per cent in time in this record. The left lower chart shows the worst part of an identical observation in the same patient during a five minute run while receiving parpanit®. The right lower chart shows the minimal activity, which occurs for 30 per cent of the time. Amplifier gain, electrode placement and position of the patient are identical in both examinations.

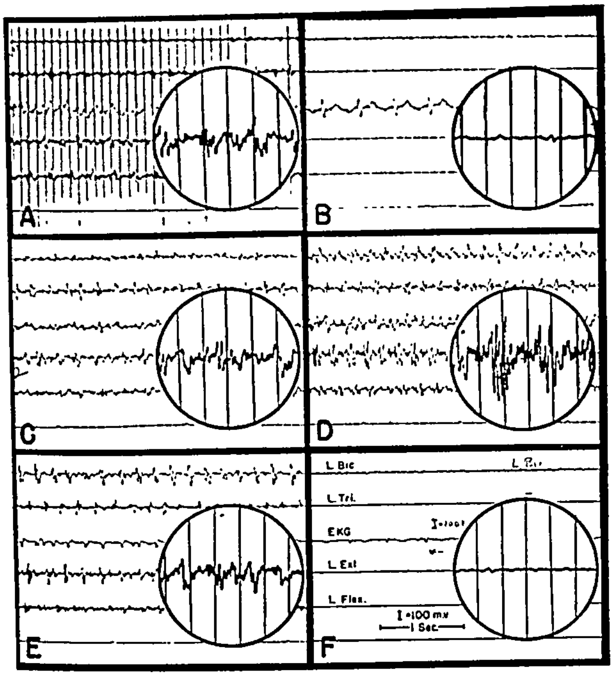
The electromyographic examination consisted of two parts:

A. A five minute resting period, with the patient sitting in the identical position on each visit, in the same chair, with the same electrode placements. No effort was made to relax the patient or disturb him during the period of resting observation. The amount of discharge, whether it be from tremor or the rigidity of the muscles, appeared then in four muscles during this period. The muscle that was quantitatively integrated during this period was always the same one in an individual patient.

B. Passive flexion, extension, pronation and supination of the resting muscles while the electromyogram was being recorded. In the assessment of the electromyogram there were three sets of data that could be brought out besides the general appearance of the record: (1) the number of clicks per five minute period from the quantitation of the integrator, (2) the number of seconds in the five minute period of minimal activity in relation to the total three hundred second time and (3) the amount of discharge from passive motion. An example of the difference in electromyograms in a case in which the condition was successfully treated with parpanit® is shown in figure 2. We have also observed, both clinically and in the electromyogram, the effect of intravenous administration of parpanit® (9 cases), comparing it with scopolamine and isotonic sodium chloride solution given intravenously under standardized conditions. Scopolamine, ⅟₅₀ grain (1.2 mg.) given intravenously, eliminated the tremor but produced confusion and drowsiness. Isotonic sodium chloride solution had no effect, while 50 mg. of parpanit® eliminated the tremor and, in this case, produced no untoward symptoms or signs (fig. 3).



3.—The electromyogram in an [illegible] postencephalitic Parkinson's disease) during [illegible] of scopolamine, isotonic sodium chloride solution and parpanit® on three different days. On the left hand of the chart, the tracings before the injection show discharges from four muscles and electrocardiogram at rest. The circular insert represents an enlargement of three diameters of the electromyogram from the extensor muscles of the wrist (line 4 on all charts) to bring out the detail which was superimposed over the corresponding point in the photograph. On the right is the electromyogram after the intravenous injection of the three drugs mentioned. All amplifier gains, electrode placements and position of the patient are identical and calibrations are on the lower right. Scopolamine A and B, ⅟₅₀ grain (1.2 mg.) eliminates tremor but produces confusion and drowsiness. Isotonic sodium chloride solution (5 cc.) causes no effect (shown in C and D). Parpanit®, 50 mg. in 5 cc. sterile water, also eliminates the tremor and does not affect consciousness, as shown in E and F.

7. It was felt that some quantitation of the rate of voluntary movement should be measured at each visit. A simple counting device was set up consisting of two insulated electrodes, one placed on the index finger and the other on the thumb. These two electrodes were connected to a low voltage counting device. The patients were instructed to touch alternately the two electrodes together and then open fully the two digits as fast as possible for a period of ten seconds (stop watch). The number of clicks per ten second period appearing on the counter were then calculated for each second, and the data for each hand were called the right and left finger-thumb rate (F. T. R.). In addition, the patient's usual gait was measured over a 10 meter distance, and this rate was timed with a stop watch and reduced to meters per second.

8. A sample of handwriting was obtained from every patient on each visit and was available for comparison.

9. Placebo and substitution effect: This was stressed in the introductory paragraph as an important criterion for successful evaluation of the new drug. It was arranged in the following manner in this investigation:

After the patients had been initially adjusted to the tablets of the new drug, they were told that further alterations in dosage were necessary and that this would be arranged by giving them capsules of different strength. These capsules were made up in the hospital pharmacy identical in size and appearance and were labeled parpanit® A, B, C and up to H. Parpanit® A, D, F and G contained parpanit® compound, 25 mg., 12.5 mg., 100 mg. and 75 mg., respectively. Parpanit® B contained scopolamine, 0.6 mg. Parpanit® C was the placebo containing calcium lactate. Parpanit® E contained stramonium, 500 mg., and parpanit® H 100 mg. of stramonium. These capsules, owing to the color of the stramonium, would appear slightly different from the parpanit® and in one series of observations a parpanit® capsule containing 50 mg. of the drug was colored artificially with mint leaves in order to appear like the stramonium capsule, but otherwise the tablets were identical in appearance. The method of the placebo trial was to substitute the parpanit® capsule for the tablet, then switch to the placebo, then back to a parpanit® capsule, then to the capsule containing the drug that the patient received prior to his investigation and then back to a parpanit® capsule. It was planned that the patients should take the different capsules for periods of four to seven days each. A comparison of how this therapy works is shown in figure 4, and it is seen that the placebo effect is specific in both patients and that the substitution of the former drug in the place of the parpanit® produces a disturbance in the welfare of the patient who is dependent on parpanit® and a slight rise in the patient in whom parpanit® produced no benefit. It is important at this point to stress the disagreeable results of placebo substitution; after we had clearly established its benefit in the first 20 cases, we eliminated this disagreeable test in the remainder. Patients who were doing well with parpanit® and were happy with the improvement would suddenly find on switching unknowingly to the placebo that not only had all of their symptoms returned suddenly but that they were overwhelmed by the notion that the medicine had suddenly become unsuccessful or that their disease had a severe exacerbation. Invariably frantic telephone calls on the part of the patient or relatives within a day or two would confirm the positive placebo effect, and we would allow the patient to resume treatment with parpanit.® It was not usually necessary to continue treatment with the placebo for more than one or two days. Some of the patients were so disturbed by this placebo effect that they were clinically set back and required several weeks of readjustment and the promise that the test would not be repeated in the future. All patients understood the necessity for this test and bore no ill will toward the investigators, but it is a very drastic method in severe chronic illness to ascertain the effectiveness of a medication.

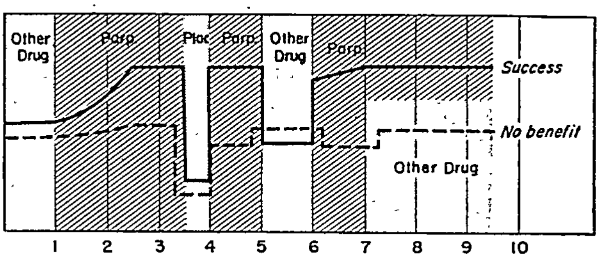


Fig. 4.—The comparative trend of the effects with other drugs (the usual antispasmodics, as scopolamine and belladonna), parpanit® and placebos. The horizontal line and figures represent the time in weeks and the vertical line the aggregate of effects that for obvious reasons cannot be numerically evaluated, but only roughly indicated as on chart. The unbroken line represents successful treatment in a case and the broken line unsuccessful treatment in another case.

10. Wherever we could, which was in over half the patients, we obtained the opinion of an outside medical observer as to how the patient was progressing. In some cases this was the referring neurologist, but in most of them it was the family physician. We felt that this was important to strengthen the medical impression as to the success or failure of this compound.

Table 3.—*Evidence of Overdosage*

| Symptom | No. of Patients |
|---|---|
| Giddiness | 20 |
| Nausea, epigastric burning | 6 |
| Weakness or light feeling in legs | 4 |
| Floating feeling (unreality sensation) | 5 |
| Headache | 2 |
| Excess perspiration | 1 |
| *Dryness of mouth* | 1 |
| Blurred vision | 2 |
| Severe constipation | 1 |

## ADMINISTRATION

In all cases parpanit® was given by mouth, in tablet form. Treatment was started with the new drug in one of two ways. If the disease was moderate or mild and the patient had not had severe symptoms previously while receiving no medication, their usual medication was stopped abruptly and treatment with parpanit® was started. The other method was used in cases of severe disease or patients that would be severely affected by no medication at all for a short period of time. These patients had their regular medicine gradually reduced over a period of three or four days while the parpanit® was gradually increased. The method of administration was as follows: Patients were told to take ¼ tablet (12.5 mg. of parpanit®) every three hours during the day for the first day. This was increased to ¼ tablet and ½ tablet (25 mg.), alternating every three hours on the second day, and further increased to ½ tablet every three hours on the third day. Incremental increases of this order continued until the patient showed definite evidence of overdosage, such as mild dizziness or other symptoms mentioned in table 3. Then he was instructed to reduce the dosage to a level that would not produce the toxic symptoms. It was usually possible to get the dose up to the maximum tolerable amount within a week or ten days. In some patients who seemed sensitive to the drug, a longer time was taken to reach this level. In patients who showed no toxic symptoms and benefit that was not sustained during the three hour period, dosage was alternated so that the tablets were given every two hours. Patients were carefully instructed to discontinue the medication if any severe reactions occurred. It was soon evident that the action was short lived and that a two or three hourly dosage was necessary throughout the day. Taken on a fasting stomach, parpanit® proved likely to cause nausea or a burning sensation in the epigastrium. Tablets taken after food or with 2 glasses of water did not cause this symptom.

Dosage has ranged from 90 to 600 mg. per day, given in divided doses, preferably every three hours, but at most every two hours. The average dose we find to be from 200 to 400 mg. per day, which represents one 50 mg. tablet five times a day. There is a wide range of individual variation in the tolerance to parpanit®; the reason for this is not clear at the moment.

Toxic effects, by the nature of the method originally employed by us, described in a previous paragraph, were frequent and occurred in two thirds of the patients. However, in only one fifth of the group was it necessary to stop treatment on this account. The commonest complaint was of "giddiness"—a sensation of lightness or "swimminess" in the head, with no vertiginous elements. Nausea and epigastric "burning" were next in order, with other complaints of a feeling of lightness of the legs, or a sensation of floating (table 1).

## CASE MATERIAL

Bedridden and institutionalized patients were not accepted for treatment, all cases being referred from the practice of the Massachusetts General Hospital. Twenty-one of the 50 patients were referred to us through successfully treated patients or their relatives. In 40 per cent of the group symptoms had been present from one to five years, in 32 per cent from five to ten years and in 28 per cent over ten years. There was a fairly close correlation between the duration of symptoms and the severity of the syndrome. Of the 50 cases, the condition was postencephalitic in nature in 38 and arteriosclerotic in 7 and in 5 it was considered to be paralysis agitans. All had been treated with one, or all, of the substances available for this condition.

## RESULTS

The results to date may be seen in figure 4. In 62 per cent of the cases parpanit® proved to be the drug of choice as compared with the usual range of substances available for the treatment of this condition; 16 per cent of the group were worse while receiving parpanit,® and in the remaining 22 per cent the effect of the drug was similar to that experienced with scopolamine or stramonium.

As for the diagnostic groups, parpanit® would appear to be equally valuable in postencephalitic parkinsonism and paralysis agitans, but of doubtful value in parkinsonism associated with arteriosclerotic disease. Patients in this group were unable to tolerate the drug.

The improvement is mainly subjective, rarely exceeding a 25 per cent level. Rigidity in particular is diminished, resulting in an increased freedom and speed of movement, with greater ease in feeding and talking. Tremor is diminished, but this change is less striking than the diminution in rigidity—although numerically approximately one half of the group noticed a decrease in tremor and one half a decrease in rigidity.

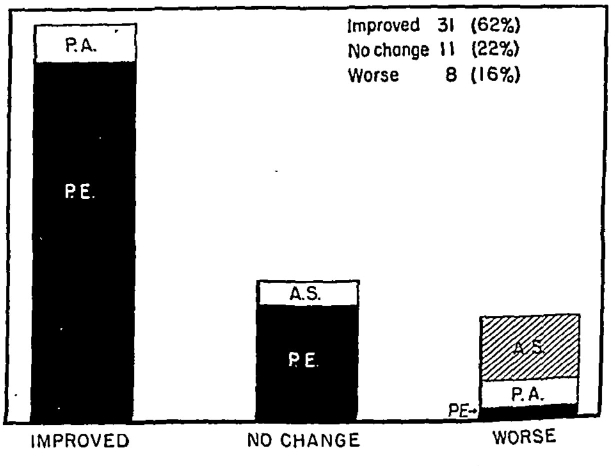

Fig. 5.—Results of treatment with parpanit® in 50 cases.

As previously stated, we were anxious to obtain objective evidence of failure or success in using this drug, and in the list of criteria a number of objective tests were mentioned. It was disappointing to us that there were not striking differences in all of these when the patients were improved. For example, the handwriting on superficial inspection in half the patients was unaffected. In over half of the patients the electromyogram showed only slight evidences of improvement after the patients were well adjusted with respect to the medication. The posture, even when measured as mentioned previously, changed in only one tenth of the patients, an amount that could be measured quantitatively. The gait, even though measured repeatedly, and in spite of a subjective report of improvement in walking, was not a striking quantitative proof of improvement. The finger-thumb rate in patients who responded favorably usually followed the clinical improvement and was a valuable guide in the assessment of success or failure. For example, a patient receiving scopolamine when first seen by us had a finger-thumb rate of 2 in each hand, this gradually increased in frequency as adjustment with parpanit® took place, and when she left this area at the end of a month her finger-thumb rate was up to 5.4 per second on each side. We felt that the changes of one tenth or even three tenths were not significant, but changes of more than this represented an improvement in speed. It was almost impossible to demonstrate improvement in the amount of rigidity and cogwheeling that was observed by the investigators. The most reliable indicators of improvement were from reports of relatives and patients on an increased ability to do the usual chores of life. These might not fit into the category of objective measurements as they were not done in the laboratory, but they are certainly not subjective. We did measure with a stop watch the time that the patient would take to get out of a chair. In some cases this gave us evidence of improvement. For example, 1 patient took 8 seconds before he was given parpanit® and was able to do it in 1½ seconds after treatment. We have kept all of this objective data in our files and expect in a later report to be able to make full correlations and statistical tables involving them. At the moment the most striking factors of success in these patients are their subjective report of well-being, the accounts from patients and relatives of a number of improved performances in leading their normal lives, which are very difficult, of course, to quantitate, and results in approximately half of the objective tests which we used. Since each patient had at least five objective measurements at each examination, we felt that we had evidence obtained in the laboratory of improvement that went along with the reported changes that were already mentioned.

## REPORT OF CASES

Case 1. *Favorable Response to Parpanit.®*—Mr. J. R., aged 29, noted the onset of tremor of the right hand, associated with stiffness and clumsiness, in 1941 (age 22). Symptoms progressed slowly and included stiffness of both legs, which was somewhat more pronounced in the right leg. There was no history of encephalitis, but the patient had had a severe attack of pneumonia at the age of 3. On examination, the patient presented the signs of a severe parkinsonian syndrome, with shuffling gait, immobile facies, decided cogwheeling and rigidity of both upper limbs, somewhat more pronounced on the right, and rigidity of both lower limbs. He had been treated with stramonium (six months), a preparation containing belladonna alkaloids (three years) and neostigmine. He found that life was very unpleasant while he was taking the belladonna preparation, owing to excessive dryness of the mouth and nose, blurring of vision and dilatation of the pupils.

On April 28, 1948, treatment with parpanit® was begun, a stabilizing dose of 300 mg. per day being reached (one 50 mg. tablet six times a day). He was still receiving this amount at the time of writing. The patient and his relatives reported that he is 25 per cent better than when he was receiving the belladonna preparation. He now shaves and dresses himself, moving more quickly and with greater ease. Neurologic examination showed little change, but there had been a steady increase in the finger-thumb rate (from 1.7 to 4.7 on the left and from 1.9 to 3.3 on the right) and in his rate over the 10 meter course. The electromyogram, however, showed little change.

Case 2. *Unfavorable Response to Parpanit®.*—Mrs. E. DeP., aged 41, a housewife who had suffered from influenza in 1918, noticed in 1943 the onset of stiffness and clumsiness of the left arm, followed by tremor. In 1945 stiffness of the left leg developed and in 1947 stiffness of the right arm. The condition had been diagnosed in 1943 as postencephalitic parkinsonism and had been treated with stramonium, scopolamine and Bulgarian belladonna. Dizziness, palpitation and weakness were noted with all these drugs. She was, therefore, referred to us for treatment. On examination she showed the classic signs of parkinsonism of severe degree, being barely able to walk unaided. Treatment with parpanit® was begun, but in spite of careful and repeated attempts to stabilize her, she was unable to tolerate the drug, complaining of dizziness, tachycardia and faintness with amounts as low as 75 mg. daily. Treatment with the drug was therefore discontinued.

## COMMENT

During the period of this investigation we had informal reports from other investigators, some of whom had had discouraging results with parpanit.® In communicating with them we found in general that the drug was being administered only two to three times a day and in rather large amounts, treatment being started with doses as high as 25 to 50 mg. Furthermore, in some instances the old medication was abruptly discontinued and parpanit® substituted. We have found that except in patients with mild disease who do not object or regress far when their previous drug is omitted, it is best to overlap the administration of the old medicine with parpanit.® There are several advantages to be gained by this maneuver. The first is that the patient is not suddenly deprived of his supporting drug and the abrupt change is avoided. After the parpanit® is administered in very small amounts, sudden removal of the previous medication may result in a period of several days in which the patient is severely incapacitated and miserable before the parpanit,® by adequate dosage, is effective. This is avoided by the overlapping method. The other advantage is that there are a number of patients who ultimately fare best on a combination of parpanit® and belladonna compounds, amphetamine or diphenhydramine hydrochloride (benadryl hydrochloride®), along with parpanit.® By using the overlap method we can gain an immediate notion as to the efficiency of the combined drugs in a particular patient.

The method that we have been using is to start the treatment with as little as 12.5 mg. of parpanit® five times a day in addition to the previous medication. The previous medication then is reduced slowly in quantity and strength and the parpanit® is slowly increased. We prefer to increase the parpanit® dosage in alternate steps so that on the second day after the initial 12.5 mg. five times a day the patient would take 12.5 mg. and 25 mg. alternately throughout the day. On the third day 25 mg. could be taken five times a day, and so on. The increments are 12.5 mg. (or ¼ of a tablet). After four to five days with this method the old medication is completely removed and the patient is then receiving parpanit® alone. The dose is then increased slowly until the mildest form of toxicity is experienced. Then the dose is reduced to a level where side effects are absent or minimal. From then on this medication is continued for a reasonable time, several weeks or months, and the patient's status reassessed and, if there is evidence that combining the parpanit® with other drugs increases the well-being of the patient, this is then done.

This report deals with the use of parpanit® alone; the combination of parpanit® with other drugs and the comparative effect of parpanit® and some of the other new drugs, namely, artane,® and diparcol® (proprietary antispasmodics), myanesin® (3-orthodoxy-1,2-propanediol) and various antihistaminic drugs, such as diphenhydramine hydrochloride, will form the basis for a second communication, which is now in preparation.

We have also noted in a number of patients that mild symptoms of overdosage with parpanit® will sometimes disappear after a week or so if this same schedule is maintained. Whether the patients learn to disregard the slight side effects or whether the side effects disappear by a mild degree of tolerance is not clear at the present time. It is well to remember that this may occur in any patient, and, therefore, if the beneficial effects of the drug outweigh the side effects in a given person, it might be well to postpone reduction of the drug for a week or so.

As stated before, we have not seen any evidence of the development of a tolerance for or addiction to this drug in any patient. We would again like to stress that the main effect of parpanit® is the reduction of rigidity and that its effect on the tremor is only mild and partial and is a secondary effect of rigidity reduction. The belladonna compounds seem to have a far more specific effect on the reduction of tremor, and it is for this reason that the ultimate regulation in the usual case of parkinsonian disease will be best achieved with combinations of drugs each of which takes care of a specific symptom.

### CONCLUSIONS

Parpanit® (diethylaminoethyl-1-phenylcyclopentane-1-carboxylate hydrochloride) has been used in 50 patients with Parkinson's disease during the past year. The effect of the drug has been measured quantitatively, subjectively and in control with placebo medication and the substances that the patients had received previously. Treatment with the drug was observed to be superior to the previous medication in 65 per cent of this group of patients. The degree of improvement was usually around 25 per cent. It is essential that one administer the drug cautiously in divided doses five times a day and watch carefully for side effects from overdosage. If this regimen is followed, very satisfactory results with this new compound will follow.

### ADDENDUM

Since this work was completed, we have tried parpanit® in 4 bedridden patients, who were not helped significantly in any way. We again emphasize that such success as we have had has depended on detailed individual regulation and supervision in each case in a manner that is similar to the individual dietary and insulin regulation for diabetes.

# STREPTOMYCIN IN THE TREATMENT OF TUBERCULOSIS

KARL H. PFUETZE, M.D.
Cannon Falls, Minn.
and
MARJORIE M. PYLE, M.D.
Rochester, Minn.

Within a year after the discovery of streptomycin was announced,[1] Hinshaw and Feldman had proved, both experimentally and clinically, that this antibiotic has a unique suppressive effect on tuberculous infections.[2] During the last three years, the results of early investigations at the Mayo Clinic and at Mineral Springs Sanatorium have been confirmed by many other investigators.[3] Thousands of persons with tuberculosis have been treated with streptomycin at many different institutions, much of the work being carried on by the American Trudeau Society, the United States Public Health Service and the Veterans Administration. As a result of this concerted attack, many of the problems connected with streptomycin therapy should be solved in the near future.

So many types of tuberculous infection have responded in some degree to treatment with streptomycin that use of the drug almost could be said to have diagnostic significance. In practice, however, it is important to limit the use of streptomycin to conditions in which, to the best of present knowledge, it is clearly indicated.

### EXTRAPULMONARY TUBERCULOSIS

Treatment with streptomycin certainly is indicated in every case of disseminated tuberculosis and should be instituted as early in the course of the disease as possible. In tuberculous meningitis, the ultimate mortality rate may not be decreased by more than a small percentage, but the remission effected by chemotherapy is often dramatic and may persist for many months. In a number of the cases in which the termination was fatal, death has been attributed to internal hydrocephalus caused by blocking of the median and lateral foramens by fibrinous exudate. Madigan and his colleagues [4] suggested that this disaster possibly can be avoided by the daily intrathecal injection of heparin.

In generalized miliary tuberculosis without meningeal involvement, remission has occurred with considerable consistency, and in a sizable proportion of cases the process remains arrested for as long as two years after

the termination of treatment. In disseminated tuberculosis, as in malignant lesions, the success of treatment probably will be gaged by the percentage of two, three and five year survivals.

Cutaneous sinuses of tuberculous origin have healed with truly remarkable consistency during treatment with streptomycin, and recurrences are infrequent. Associated lymphadenitis tends to become quiescent. When bones or joints are the foci of infection, orthopedic surgery may be performed successfully after healing of the sinuses. Treatment with streptomycin is not so uniformly effective in tuberculous pleural fistulas, although it has brought about healing in more than half of such lesions. Anal fistulas may heal during treatment with streptomycin, but fistulas of long duration are likely to be refractory to chemotherapy.

Streptomycin therapy already is accepted as the most effective treatment known for ulcerative and granulomatous lesions of the oropharynx, larynx and tracheobronchial tree. When pain and dysphagia are present, the patient usually is relieved of the symptoms within a week after chemotherapy has been started, and healing of the lesions as a rule is complete after a few weeks of treatment. The percentage of recurrences is small.

In tuberculous enteritis and peritonitis the results of streptomycin therapy have been consistently favorable. In enteritis, symptomatic improvement usually occurs within a week or two after treatment was begun, and eventually there may be roentgenographic evidence of healing.

Treatment with streptomycin has brought considerable relief to many persons suffering from genitourinary tuberculosis. Alleviation of symptoms occurs in nearly all cases and often is prolonged. Associated sinuses generally heal, and often there is healing or decided regression of lesions of the bladder. Although there is seldom any change in renal damage as demonstrated by pyelography, the urine becomes free of tubercle bacilli in a high percentage of cases.

In early investigations it seemed that the bacteriologic conversion usually was temporary. However, as the number of patients treated has been increased, the percentage of persistent conversions has proved to be greater than had been expected. Units of the Veterans Administration for the study of streptomycin[5] report that, in a total of 54 cases in which the urine became free of tubercle bacilli, the organisms could not be recovered by culture or inoculation of guinea pigs in 46 cases since termination of the treatment; in 39 of these cases, the period elapsing since cessation of chemotherapy ranged from twelve to fifty-two weeks.

In a few of our patients who had renal tuberculosis, the disease has remained arrested as long as two years after the termination of treatment. However, since there is no certainty of permanent arrest, treatment with streptomycin must not be substituted for surgical procedures which may result in a real cure, although chemotherapy may be of value as preoperative and postoperative treatment.

Streptomycin appears to have a limited but definite place in the treatment of tuberculosis of bones and joints, employed either alone or in conjunction with surgical treatment.[6] Subsidence of local signs and symptoms may be complete in early stages of the disease; but only occasionally is improvement evident in the roentgenographic appearance of lesions.

Streptomycin is proving to be a great boon in the treatment of tuberculous otitis media. Occasionally, the drug has been used successfully in tuberculous pericarditis. In ocular tuberculosis the value of chemotherapy is suggested but not established. In cutaneous tuberculosis, the benefits of treatment with streptomycin may be striking, but are more likely to be variable or temporary. Streptomycin has not altered the prognosis of lesions located in the brain. The substance of the brain is impermeable to streptomycin, possibly because the drug is water soluble, whereas brain tissue contains a high percentage of lipids.

Despite the tendency of tuberculous pleurisy with effusion to regress spontaneously, we believe that a brief period of chemotherapy often is indicated in this condition. When streptomycin is administered, evidence of toxemia tends to disappear within a few days, and it seems reasonable to anticipate a lower incidence of complications and recurrences. We make the reservation, however, that in this condition the period of chemotherapy can and should be brief, usually not longer than two or three weeks.

In contrast, treatment with streptomycin has been found to be relatively ineffective in tuberculous empyema, except in an occasional case. Pleural fluid has been found to contain an adequate concentration of streptomycin when the drug is injected intramuscularly, but in empyema the fluid generally is highly acid, whereas streptomycin is most effective in a medium which is neutral or slightly alkaline in reaction.

### PULMONARY TUBERCULOSIS

In the treatment of pulmonary tuberculosis with streptomycin, the necessity for careful selection of patients must be emphasized. In this large category of tuberculosis in human beings, the pathologic changes are so diverse and the host-parasite relationships are so variable that the same antibacterial agent may produce a therapeutic effect in one situation and not in another. In theory, chemotherapy can be expected to be most effective in those pulmonary lesions which are accessible to the blood stream and which are not characterized by irreversible anatomic changes. In practice, streptomycin has proved to be most useful in the treatment of such lesions. They are usually recent lesions, predominantly exudative in character, and often are due to hematogenic or bronchiogenic dissemination.

Chiefly for the very reason that streptomycin has proved to be so valuable in certain tuberculous conditions, we believe that it should not be used in cases in which the prognosis without chemotherapy would be favorable. Because of the phenomenon of bacterial resistance, there is no certainty that streptomycin will exert its suppressive effect for more than one period of treatment. No one needs to be reminded that tuberculosis tends to be a chronic and recurrent disease. To use streptomycin unnecessarily may be tantamount to wasting therapy for which later there may be real need.

Hence, we believe that streptomycin should not be used in minimal pulmonary tuberculosis or in any other tuberculous condition for which other satisfactory treatment is available. Moreover, we doubt the wisdom of the use of streptomycin indiscriminately for prophylactic purposes. For instance, after pulmonary hemorrhage we believe it is preferable to administer streptomycin if and when there is evidence of bronchiogenic dissemination rather than to prescribe the drug routinely, solely as prophylaxis.

Accurate appraisal of the condition of each patient is always necessary in the treatment of pulmonary tuberculosis. Streptomycin should be prescribed only as part of a far reaching plan to bring the patient's disease under lasting control. It is most important that chemotherapy be correctly timed in respect to other therapeutic procedures which may be planned. When collapse therapy or pulmonary resection is indicated, it is advisable to institute the procedure at a time when the patient has received sufficient benefit from chemotherapy but, if possible, before the occurrence of bacterial resistance.

As yet there is no proof that drug-resistant tubercle bacilli are either more or less virulent than drug-sensitive organisms. The significant fact is that, after bacterial resistance has appeared, the suppressive effect of streptomycin is lost, and the patient again is dependent on his own forces of defense. If these are inadequate, there is danger of relapse or extension of disease. Therefore, by the use of any other therapeutic resource which may be indicated, the opportunity must not be lost to fortify a drug-induced remission.

Unquestionably, chemotherapy has increased possibilities for the surgical treatment of pulmonary tuberculosis. By causing resolution of exudative lesions, especially in the contralateral lung, and by improving the patient's condition by reducing toxemia, treatment with streptomycin may make thoracoplasty or pulmonary resection[7] possible. The chief and possibly the only valid indication for the use of streptomycin in fibrocaseous and fibrocavernous disease is as an adjunct to surgical treatment. In acute pneumonic processes, pneumothorax probably can be established more promptly and more safely after a course of streptomycin than would otherwise be possible.

### ADMINISTRATION AND DOSAGE

Streptomycin is administered parenterally, by intramuscular or deep subcutaneous injection. In patients having tuberculous meningitis treated at the Mayo Clinic, remission has been sustained only when the drug was administered intrathecally as well as intramuscularly. Most investigators have agreed that intrathecal administration is necessary, but uniform opinion as to the amount and duration of such treatment has not been recorded.

The evidence indicates that intramuscular administration alone gives satisfactory results in all other types of tuberculosis amenable to chemotherapy, and, in fact, this may prove to be the only practical method of administration. Even when lesions are accessible to local treatment with streptomycin, topical application by itself seems to be relatively ineffective.

The optimal dose and the optimal duration of treatment cannot be stated positively at present. In early investigations doses of from 1 to 3 Gm. a day were given for two to six months. It now appears that in most cases the therapeutic effect can be produced and untoward results are less likely to occur when the dose of streptomycin is relatively small and the period of treatment is relatively brief. A dose of 0.5 Gm. a day often produces a therapeutic result in more responsive types of tuberculosis.

It has been found that the frequency of administration can vary greatly. When the total daily dose is at least 1 Gm., results apparently are comparable, whether the drug is administered at four, six, eight, twelve or twenty-four hour intervals. Studies now in progress indicate that the entire daily dose of streptomycin can be given in one injection without sacrifice of therapeutic effect.

The latitude apparently permissible in frequency of administration is unexplained. Streptomycin is excreted rapidly, and, to maintain a bacteriostatic concentration in the blood, administration as often as every six hours probably is necessary. It has been suggested that in relatively large doses streptomycin actually is bactericidal[8] and that infrequent administration is effective because with each dose a proportion of the bacterial population is destroyed.

### BACTERIAL RESISTANCE

It is not yet known whether dosage in streptomycin therapy has any relation to the rate of occurrence of bacterial resistance. Duration of treatment, however, probably is a major factor. Serial cultures of patients' sputum have shown that a few tubercle bacilli relatively resistant to streptomycin are present before exposure to the drug and that, during treatment, the resistant organisms increase in number and in the degree of their resistance.[9] In approximately three fourths of all cases, the bacterial population has been predominantly resistant after six to sixteen weeks of treatment; occasionally, resistance has been noted as early as the thirtieth day of treatment.

It is impossible, in any given case, to predict how soon resistance will appear or how long it will persist after it has appeared. In 1 case in our series, bacilli resistant to 3,000 micrograms of streptomycin per cubic centimeter of medium could be recovered from the patient more than three years after cessation of treatment. In a very few patients under our observation, strains predominantly resistant have been replaced by sensitive strains when medication was discontinued.

Since the probability of occurrence of resistance increases as treatment is prolonged beyond six weeks, the consensus is that, in most cases, the duration of chemotherapy should be limited to five or six weeks and, occasionally, to even briefer periods. Suppression of an infection for a few weeks often is sufficient to enable the patient's natural powers of defense to become ascendant. If relapse occurs, treatment can be resumed if the infecting organisms are still sensitive to streptomycin in vitro. If the bacterial strain has become drug resistant, prolongation of the original period of treatment would be useless anyway. When it is possible to carry out laboratory tests for the rapid and frequent determination of resistance in vitro, it should be possible to gage duration of treatment on this basis.

Little is known of the factors concerned in the production of bacterial resistance. Variation in the concentration of streptomycin to which foci of tubercle bacilli are exposed may be a factor. In a case at the clinic, bacilli extremely resistant to streptomycin were recovered from the patient's sputum after chemo-

therapy, but when this patient came to necropsy, a perivesical abscess was found to contain bacilli which were as sensitive to streptomycin as the original strain had been. McDermott and his associates[10] mentioned two instances in which streptomycin-sensitive bacilli were isolated from the cerebrospinal fluid of persons who were discharging drug-resistant organisms from other lesions.

One of the patients in our early investigation was treated with streptomycin in preparation for pneumonectomy. After six weeks of treatment, bacilli resistant to 3,000 micrograms per cubic centimeter of medium were recovered from the patient's sputum. After pneumonectomy, the patient continued to discharge tubercle bacilli. However, these organisms were much less resistant, cultures being inhibited by from 25 to 100 micrograms of streptomycin per cubic centimeter of medium. Evidently the resected lung, which contained a huge cavity, had offered optimal conditions for the production of resistance.

Methods are being sought for the prevention or delay of the occurrence of bacterial resistance. Recently, investigators at Fitzsimons General Hospital[11] reported a study in which 16 patients received intermittent treatment, 2 Gm. of streptomycin being given in one day at intervals of two, three, four or five days, for a total elapsed time of one hundred and twenty days. With these schedules, only 1 of the 8 patients whose sputum continued to contain Mycobacterium tuberculosis discharged bacilli which were streptomycin resistant; of 8 patients who received the drug at three day intervals, there were 5 whose sputum continued to contain M. tuberculosis, but none of these 5 discharged resistant organisms.

Although this series of cases is small, the low incidence of bacterial resistance is distinctly unusual. Moreover, despite these schedules of discontinuous treatment, a definite therapeutic effect was produced and in no case was there subjective evidence of toxicity. Work by Youmans[12] has indicated that in vitro the tubercle bacillus divides at intervals of from thirty-six to eighty-four hours. The rate of multiplication in the human body must be very variable, but if streptomycin is effective when it is given at intervals of two or more days, it would seem that the drug acts by inhibiting and possibly by destroying those bacilli which are in a susceptible stage of reproduction.

Another method of attack against the problem of bacterial resistance consists of the simultaneous administration of two or more agents which are antibacterial so far as M. tuberculosis is concerned, on the assumption that organisms naturally resistant to more than one compound should occur with extreme rarity. In a series of 70 cases of tuberculous meningitis, Cocchi and Pasquinucci,[13] of the University of Florence, used streptomycin and "promin" (sodium p,p′-diaminodiphenylsulfone-N,N′didextrose sulfonate) in combination; they stated that when this regimen was employed, bacterial resistance to streptomycin did not occur. In studies in progress at our own institution and at other institutions, streptomycin is being administered together with "promin" and para-aminosalicylic acid.

If use of a combination of antibacterial agents prolongs the suppressive effect of these agents by preventing or postponing the occurrence of bacterial resistance, the patient should have commensurate opportunity to overcome his disease. Furthermore, it has been suggested that, used in combination, antibacterial compounds may have an additive therapeutic effect. In experimental tuberculosis, Smith and McClosky[14] reported better results from the use of streptomycin and "promin" together than from the use of either drug alone. Recently, Lincoln and her associates[15] reported on the use of "promizole" (4,2′-diaminodiphenyl-5′-thiazolesulfone) together with streptomycin in the treatment of tuberculous meningitis. As yet, insufficient time has elapsed for it to be possible to determine whether results are better with this combination of agents than could have been expected with the use of streptomycin alone.

## TOXICITY

The potential toxicity of streptomycin no longer is of great moment, since it has been learned that in most cases the therapeutic dose of the drug is appreciably less than the toxic dose. When the dose is relatively small and when the patient's renal function is adequate to preclude the occurrence of high concentrations of streptomycin in the blood, evidence of toxicity is minimal. Only a small proportion of patients receiving a total daily dose of 1 Gm. or less have shown the vestibular dysfunction which is a common occurrence when larger doses are used.

With regimens in use at present, the potential toxicity of streptomycin is chiefly a matter of a patient's idiosyncrasy or acquired sensitization to the drug. Reactions of sensitization usually appear after treatment for one week to three weeks, with manifestations of fever, nausea, cutaneous eruptions, pruritus and eosinophilia. Temporary withdrawal of streptomycin is necessary for the abatement of reactions of any severity, but most patients will tolerate the drug after a rest period, particularly if desensitization is carried out.

Among nearly 1,000 patients treated by the medical services of the Army, Navy and Veterans Administration,[16] isolated instances of serious toxic effects have occurred. Three cases of exfoliative dermatitis have been reported, 1 case of granulocytopenia and 2 cases of aplastic anemia[17] in which streptomycin was suspected of being a precipitating factor.

It appears that streptomycin can be used with comparative safety in pregnancy. In a small series of cases we have administered a dose of 0.5 Gm. daily for three to five weeks during the third trimester of pregnancy. In all cases the mother has received appreciable benefit from chemotherapy, and the infants have appeared normal at birth; their labyrinthine function will be ascertained when caloric tests can be performed.

It is obvious that special care must be used in the selection of pregnant patients for streptomycin therapy. The effect of the drug on fetal development early in gestation is not known. The mother's need of chemotherapy, the potential toxicity of the drug for the infant, the risk of terminating pregnancy and the availability of other therapeutic measures are all factors which must be considered in the management of any patient.

### SUMMARY AND CONCLUSIONS

In the last four years streptomycin has become an important therapeutic resource in tuberculosis. In some tuberculous conditions streptomycin is effective when it is used alone. In other conditions it is a valuable adjunct to other forms of treatment and especially to surgical procedures. It may be found that the value of streptomycin is enhanced by use of the antibiotic in combination with other agents which also are antibacterial in respect to tuberculosis. Since it has been observed that relatively small doses of streptomycin are therapeutically effective, the potential toxicity of the drug has become a minimal consideration.

The phenomenon of bacterial resistance remains the chief limitation to the treatment of tuberculosis with streptomycin. In the selection of patients for treatment, the disadvantage of the production of strains of drug-resistant tubercle bacilli must be weighed against the patient's immediate need of chemotherapy and against the probability of a therapeutic result in a given case.

Other problems, in addition to that of bacterial resistance, pend further investigation. However, the efficacy of streptomycin against tuberculous infections has proved that tuberculosis is yet another disease vulnerable to chemotherapeutic attack. Without undue optimism, greater triumphs may be anticipated.

## ABSTRACT OF DISCUSSION

Dr. George Ornstein, New York: Streptomycin has produced more results than any previously used drug in tuberculosis. Its greatest value is in acute exudative tuberculosis of the lung, in which form of tuberculosis there is frequently an underlying cavity masked by the exudative infiltration. The cavity may be overlooked when conventional roentgenograms are used. Tomograms reveal the hidden cavity in the lung. In my group such roentgen studies are made before streptomycin is given. If in three or four weeks of therapy the cavities do not close, the lung is collapsed by pneumothorax or by other surgical methods should the pneumothorax therapy fail. The streptomycin then is discontinued. There has been a change in the spontaneous closure of cavities in my series of cases. With routine rest therapy there has been spontaneous closure of 15 per cent of cavities. Since the use of streptomycin the percentage has risen to over 40 per cent. Streptomycin has an excellent effect on endobronchial tuberculosis, and, inasmuch as each cavity has endobronchial tuberculosis, the ball valve mechanism in each patent cavity produced by the endobronchial tuberculosis may be made ineffective by the use of streptomycin. After a few weeks of such treatment, pneumothorax produces more rapid collapse than would have been the case without streptomycin therapy. There were also deaths among the far advanced cases of pulmonary tuberculosis. Tomographic studies were always made in these cases, and if the cavities did not respond rapidly my co-workers and I used our previous methods of collapse therapy, which cut down the death rate considerably. We rarely continued to use streptomycin more than three to four weeks when cavitary formation was present, unless there was evidence of healing of the cavities. We have had cases in which far advanced disease was arrested with streptomycin therapy. I hope that physicians will not regard streptomycin therapy as they did pneumothorax therapy when it was comparatively new. A pneumothorax was done only in a patient who was very ill, and for two decades pneumothorax was not induced early in the disease. It appears that many clinicians have the same attitude toward streptomycin. Too much thought is given to whether the tubercle bacillus will become resistant to the drug and whether in the future an activation of the disease will occur. It may occur, but clinically it has occurred infrequently. If the disease is rapidly arrested, patients have a much better chance than if one treats them when their disease has progressed.

Dr. Donato G. Alarcón, México, D. F., Mexico: The series presented by Dr. Pfuetze to show the results of streptomycin in the treatment of tuberculosis are in accord with the results obtained in other places in the United States and in other countries. In Mexico we obtain similar results. I find the paper commendable because it presents the successful as well as the unsuccessful results with scientific honesty. I agree with the statements made by Dr. Ornstein regarding the necessity of accurate control of the presence of cavities as far as it is possible by the laminagram. Finally, I would like to know the results obtained by Dr. Pfuetze in the treatment of primary pulmonary tuberculosis in children and in adults. Results in this particular group have been very encouraging in our country.

Dr. Benjamin Potter, Jersey City, N. J.: Streptomycin offers an unquestionable favorable effect in an appreciable number of cases of certain types of tuberculosis. The drug is not a substitute for accepted measures of therapy, yet it can initiate improvement in patients who previously would not respond to any known therapeutic approach. My second point concerns the part which "tissue resistance" plays in continuing the initial favorable changes after streptomycin therapy is discontinued or when resistance to the drug develops. As Dr. Pfuetze and Dr. Pyle have shown, rapid absorption of infiltrations and remarkable clinical improvement follow in susceptible cases, and it is these alterations which apparently bring about a state of general well-being and local tissue resistance, which serve to carry on where the drug's action ceases. Finally, I am inclined to agree with Dr. Hinshaw that the dose should be individualized and that the optimum dosage will be more closely approximated if determinations are made according to the patient's weight. I think that it is too early to generalize on any one particular dosage, although studies such as Dr. Bogan's should be encouraged.

Dr. H. G. Trimble, Oakland, Calif.: In the West, we heartily agree that one should not make indiscriminate use of streptomycin. We feel that it is a potent weapon that has excellent use and should be kept for the most useful work. Streptomycin therapy does not cure tuberculosis, but it does give temporary control of the disease many times and helps the patient with acute exudative lesions who could not get well without it. Dr. Pfuetze used collapse therapy in patients who improved with streptomycin therapy, but still the sputum was culture positive. Tuberculosis cannot be well controlled in the course of six weeks or three months even when prolonged sanatorium care alone is added. My colleagues and I also are in favor of combining some form of relatively simple collapse therapy. We think that collapse is of decided benefit after streptomycin has given temporary control in those cases in which streptomycin is needed. I think that surgeons particularly will subscribe to this. One cannot always predict the course of the tuberculosis, and when one sends the patients to the surgeon for excision therapy when the patient has already had streptomycin the prognosis is much more serious.

Dr. Abel Froman, Chicago: I would like to ask Dr. Pfuetze whether he uses streptomycin in minimal lesions.

Dr. Morris Braverman, Detroit: Tuberculosis in pregnancy and the simultaneous use of streptomycin bring questions to my mind: (1) What happens to the mother, (2) what happens to the fetus, and (3) what happens to the child later? Is it born deaf?

Dr. Karl Pfuetze, Cannon Falls, Minn.: Dr. Ornstein has emphasized the necessity of treating patients with old chronic lesions. It is certainly permissible to use streptomycin for the relief of symptoms. We do not use it routinely in cases of chronic disease at present, for we cannot honestly anticipate a satisfactory result and after a few months the patient's tubercle bacilli are usually streptomycin resistant. Such patients may leave the sanatorium against medical advice and spread their tuberculosis to others. I agree with Dr. Ornstein that many patients with fresh exudative lesions should receive streptomycin soon after their admission. Occasionally we start treatment with the drug before the bed is warm. However, we are still willing to wait a few weeks or more in many cases before deciding to use streptomycin. Dr. Alarcón has asked about the use of streptomycin in primary infections. I have not used streptomycin in primary infections. In our part of Minnesota, a prosperous farming area, one rarely sees malignant primary tuberculosis in children. I would not hesitate to use it in such cases if the patient were not doing well with routine care. I do not believe that streptomycin should be used routinely for all fresh primary lesions, but I am willing to have the physicians who see many such cases give us the answer to this question. Combining collapse therapy with streptomycin is important. We have continually stressed this point, and many of our most dramatic results have occurred in cases in which streptomycin therapy was combined with necessary collapse procedures. We do not use streptomycin routinely in cases of minimal disease. Our present attitude is to decide each such case on its own merits. Later, perhaps, our opinion in this respect will be reversed. It seems to me that we must all remain open minded in our attempts to solve these problems. The use of streptomycin for tuberculosis in pregnant patients presents another problem. We do not know as yet what effect streptomycin may have on the fetus. Thus far, we have used it very cautiously for several weeks in 3 pregnant patients in doses of 0.5 Gm. daily. In each case, an apparently normal baby was born. We must wait to see what may occur in these children two or three years hence.

---

**Contraindications to Splenectomy.**—It is essential that the spleen not be removed in cases of agnogenic myeloid metaplasia because in this condition much of the bone marrow function of forming blood cells has been transferred from the bone marrow to the spleen and removal of this organ may be rapidly fatal. Competent hematologic study and bone marrow observation will quickly establish this diagnosis and any thought of splenectomy must be dismissed. With rare exceptions, splenectomy in cases of leukemia and lymphoblastoma with splenomegaly should be avoided. The exceptions include rare panhematocytopenias or hemolytic anemias of severe degree caused by hypersplenism in some of these cases. They also include cases in which the disease may still be limited to the spleen but such cases are very rare. The spleen should not be removed in polycythemia vera although rarely a case is seen in which the influence of the enlarged spleen is such as to inhibit the output of a normal number of cellular elements. It is most unusual to find splenomegalies in infections in which splenectomy is justified, although rarely the hypersplenic effect is such as to demand careful consideration of this procedure. In general, patients with paroxysmal nocturnal hemoglobinuria do poorly after splenectomy and patients with Mediterranean and sickle cell anemias are also not helped by the procedure. The technical complications of splenectomy in patients with congestive splenomegaly in which marked perisplenitis exists are of such seriousness and the benefits so problematical as to contraindicate its employment when this state is found.—Frank H. Lahey, M.D., and John W. Norcross, M.D., Splenectomy: When Is It Indicated? *Annals of Surgery,* September 1948.

# MEDICINE UNDER THE BRITISH NATIONAL HEALTH ACT

MORRIS FISHBEIN, M.D., Editor
The Journal of the American Medical Association

Long before Great Britain began to provide medical care for the people under the new British National Health Act other nations had experimented with state medicine and compulsory sickness insurance systems. A careful study of the British National Health Act indicates that it represents another attempt to make administration serve purposes in medical care which are foreign to the practice of medicine.

Under the British National Health Act which became effective July 5, 1948, Great Britain was divided into some fourteen or more areas, each of which was controlled by a regional board. These boards include representatives of all of the interests mainly concerned in the conduct of hospitals. The ultimate financial control rests with the Minister of Health. He delegates to the regional boards the responsibility of planning hospital services in their areas. They are charged not so much with the management of individual hospitals as with arranging the pattern of hospital service and determining whether or not services are adequate. The hospitals are managed by management committees in their own areas. Each hospital has, moreover, a local committee. The chain of control is from the Minister of Health to the national health boards to the management committees and from them to the house committees.

I have mentioned the control of hospitals first since modern medicine depends on the hospital as the center of medical care and since hospital costs nowadays represent the large bills which for the most part have caused the public to take a special interest in the provision of medical service. The facts that I shall present here regarding the British National Health Act are based on a trip to England early in August 1948, during which I had opportunity to view at first hand the methods of practice, to meet with representatives of the medical profession and of the Ministry of Health and to speak with patients from every class of society.

Under the new Act the Ministry of Health provides hospital and specialist services without cost, other than the tax paid by the people of England, to all who wish to enrol under the Act. The people are also provided with appliances, such as eye glasses, wigs, hot water bottles and similar materials that are not more expensive than the types prescribed by the Ministry. The hospitals may charge for part-paying patients in single rooms or wards.

The Minister of Health is advised by a central council which includes 41 persons, of whom 6 are officers of the Royal Colleges of Surgeons, Physicians and Obstetricians, the General Medical Council, the British Medical Association and the chairman of the public health office. The remaining 35 are appointed by the Minister of Health. Fifteen medical practitioners are included, 2 of whom are experts in mental disease; 5 in the field of hospital management; 5 in

local government; 3 dentists; 2 mental health experts; 2 nurses; 1 midwife, and 2 pharmacists. Thus the British have organized one of the most complicated machines for dealing with health that the world has ever known. From the data already available, the certainty exists that this monster bureaucracy removes from hospital care and medical care all of the personal spirit that has given to voluntary hospitals and individual physicians in the United States the leadership and the progress in medical science that are distinctive of our country. Moreover, the costs of the service have gone far beyond any of the governmental estimates in advance of its installation. Apparently the costs of drugs and appliances for the first three months were three times the amounts estimated by the Ministry of Health.

HEALTH CENTRES AT WHICH GENERAL PRACTITIONERS AND DENTISTS WILL BE INVITED TO PRACTICE WILL BE PROVIDED BY LOCAL HEALTH AUTHORITIES AS SOON AS BUILDING CONDITIONS PERMIT

Plan for the provision of medical care under the British National Health Act.

## THE MEDICAL PROFESSION AND THE MINISTRY OF HEALTH

American physicians have been familiar with the steps in the development of the British National Health Act and with the attitude of the British Medical Association toward that Act. Today, about six months after the service became effective, the evidence is clear that the medical profession accepted promises from the Ministry which have never been fulfilled. They accepted guarantees of certain rights under the Act which have already been violated. Certainly we in the United States should be intelligent enough to learn from that record that such promises and guarantees are without any validity.

Dr. Guy Dain, who is chairman of the Council of the British Medical Association and who with the secretary of the British Medical Association conducted most of the negotiations with the government, told the medical profession in the process of these negotiations that certain freedoms would be guaranteed by the Ministry of Health. These included freedom of choice, freedom to do state and private practice, freedom of speech, clinical freedom, freedom to regulate the list of patients and freedom to practice where the physician wished to practice, provided that he did not *select an overdoctored* area.

In a communication to the *British Medical Journal,*[1] Dr. George Rossdale questions either the attainment or the retainment of these freedoms and asserts, "Dr. Dain speaks with two voices in the same speech." "His list of freedoms," says Dr. Rossdale, "is far less formidable than his list of servitudes." Dr. Dain himself talks of the lack of medical manpower and of the manner in which physicians are being overwhelmed with trivial complaints. Dr. Dain warns that the coming winter may cause a complete breakdown in medical services. He reminds the medical profession of the Special Inducement Fund. Of course, a physician can refuse to accept a patient who applies for a place on his panel; he can decide how much private practice he would like to do; but actually there are no private patients left for 93 per cent of the general practitioners in England, and most of the medical profession are convinced that private practice represents 1 per cent of all of the practice in England. Dr. Rossdale inquires, "What is an over-doctored area?" and points out that a doctor cannot go to any area when the Ministry of Health forbids. Indeed, he concludes, "The truth is that the very opposite of freedom has been attained in fact—a state of servitude and indignity never before thrust on any profession in this country."

While in England I spent an entire morning with Sir Wilson Jameson, chief medical officer for the

---

[1] Rossdale, G.: Freedom of the Profession, Brit. M. J. (supp.) 1: 18 (Jan. 8) 1949.

Ministry of Health, and with Dr. Kennedy, his assistant. I have since had interviews with other representatives of the Ministry of Health both for England and for Scotland. When I left Sir Wilson Jameson, who is known and admired by many American friends and colleagues, he asked me whether there was any further information that he might give to me. I replied that I would be especially happy to receive a copy of each of the forms and each of the regulations used under the Act. Sir Wilson Jameson said—and he has a keen wit—"Doctor, have you chartered the Queen Elizabeth to take you home?" For some months I have been receiving each week additional forms and additional regulations. These form the basis of certain processes in the practice of medicine in Great Britain that I shall later describe in detail.

### THE MECHANISM OF THE HEALTH ACT

The administration of medical practice is, in general, central, regional and local. The Ministry of Health administers the Act. The Central Health Services Council already described provides the Minister with professional and technical guidance. The Minister has power to constitute standing advisory committees, and several of these, particularly related to the prescribing of drugs, have already been established. Regional boards act as agents of the Minister for organizing and developing hospital and specialist services within their areas, but ultimate control rests with the Minister. Detailed management of all hospitals except teaching hospitals is in the hands of hospital management committees which are appointed by the regional boards. The teaching hospitals, which are associated with universities, are managed by boards of governors who are appointed by the Minister from persons nominated by the university, the regional board of the area, the medical and dental teaching staff of the hospital, the local medical health authority and any other organization that the Minister considers to be concerned.

The local health authorities are responsible for local services, including the care of expectant and nursing mothers and young children, priority dental care for expectant and nursing mothers and young children, home midwife service, home nursing services, public health nursing in the home, domestic help where needed on grounds of health, after-care of sick persons in their homes, vaccination and immunization, and ambulance services.

A local executive council has been appointed for each local health authority area. The doctors, dentists and pharmacists who take part in the family practitioner arrangements under the Act have their contracts with the local executive council. Each local executive council includes a chairman and 24 members, 8 of whom are appointed by the local health authority, 4 by the Minister of Health, 7 by the local medical committee, 3 by the local dental committee and 2 by the local pharmaceutical committee.

The service began by asking every citizen to choose a doctor. Lists of doctors in each area participating in the scheme were posted in the local libraries and the post office. The doctor had the right to refuse to accept any patient. Patients may change doctors, and doctors may have patients' names removed from their lists. The doctor is paid according to the number of patients on his list.

When a patient joins a list, he receives a medical card. If he happens to be away from home when he becomes ill, he can go to any local doctor who participates in the scheme, present his medical card and receive treatment.

The Ministry in its propaganda stresses that this is not charity but that everyone pays for the service by taxation. Nevertheless, the word "free" is used constantly, such as in the statement that patients "receive free treatment" and ". . . medicines, drugs and appliances are to be had free from any pharmacist who takes part in the scheme." There are no hospital charges, but those who have money may pay for extra privacy in single rooms or small wards. Specialist ear clinics have been established, and the Medical Research Council invented a new hearing aid which is provided without extra cost (the propaganda bulletin says "free") to those for whom it is prescribed. Also spectacles are provided without extra cost, but fancy glasses and frames can be had on the payment of extra costs.

Since British physicians were accustomed to own their practices and to sell the good will, the Ministry of Health proposed to compensate those who lost their practices by setting aside a sum of $264,000,000 as compensation.

A physician may establish himself in any area that he chooses, provided that he does not set up a new practice in an area that has been called "overdoctored." A physician who was already in practice when the Act came into force could be paid entirely by capitation fees or by a basic salary of $1,200 a year and lower capitation fees. There are various ways in which a doctor may make a little extra money, and these will be discussed later.

In making their agreement with the Ministry to serve under the Act, the British medical profession demanded reassurance that a doctor would be free to publish his views on the organization and administration of the service. Much of the criticism that will be here cited is based on letters from physicians to the *British Medical Journal* and to the London *Lancet*, on papers already published by British physicians and on letters and documents received from agencies in England established to combat the tremendous powers that rest in the Ministry of Health.

### MEDICAL EDUCATION

At present doctors in Great Britain spend two years in a recognized medical school and then three years in a hospital or dispensary. Each student spends six months as a clinical clerk and another six months in surgical training as a dresser and in anesthetics, radiology and operative surgery. Practical instruction is also given in obstetrics, gynecology and infant hygiene, and each student must spend some time in a maternity hospital and attend under adequate supervision at least 20 cases of labor. A doctor may go immediately from this training into practice under the panel system, or he may take a residency in a hospital or act as assistant to an established physician. He may, if he wishes, spend two or more additional years qualifying for a higher degree in a specialty. Already proposals have been made to pay for students in medical schools, to make a hospital service corresponding to our internship compulsory and to demand that every specialist have at least six months' clinical experience followed by a course in a specialty lasting at least four years. The General Medical Council has also urged that more emphasis be placed on child health, psychiatry and social medicine and that instruction be added on rehabilitation.

The Ministry of Health has pointed out that every man, woman and child in the country, without any exception, is eligible for all the health services. There is no age bar, so that the service is open to old persons as well as younger ones. Five sixths of the total cost of the National Health Service comes from general taxation, and one sixth is taken from the National Insurance Fund, which is a tax on the payroll. A portion of the worker's tax covers him with cash benefits for retirement, widow's pension, unemployment and disablement pension.

In initiating the Act the Ministry of Health proposed to construct health centers in which physicians could join in the work as a team, in which there would be available surgeries and consulting rooms equipped with the latest and most efficient forms of apparatus and also comfortable waiting rooms. The available evidence does not indicate that any one of these health centers has yet been opened. Preceding the initiation of the Act, the Ministry of Health issued a considerable number of propaganda bulletins said to be "instructional."

### PRIVATE PRACTICE

By November of 1948 it was clear that the private practice of medicine in Great Britain was disappearing. As might have been expected, the Ministry did not view the disappearance of private practice with alarm. Indeed, it becomes apparent that such disappearance must have been contemplated. For instance, although a patient who consults a private practitioner is paying taxes for medical service, a chemist or druggist cannot fill a prescription for this patient without charging the patient, whereas a prescription filled for a physician working under the Act is provided to the patient without further cost.

Physicians have the greatest difficulty in securing beds in hospitals for private patients.[2] After describing the various difficulties which have developed in trying to sustain private practice, this editorial concludes, "There is no mandate in the Bill for the killing of private practice by the imposition of vicious penalties, and we suggest that the Minister and his advisers would do well to think again."

When the time came for the physicians to receive their first quarterly payments under the National Health Service, the doctors received far less money than they had anticipated. The basic salary of $1,200 was proposed by the Minister of Health but rejected by the British Medical Association. The Association considered it the opening wedge to a salaried state medical service. Some doctors wished to receive the basic salary after they discovered that they could not live on the incomes received by the capitation technic. All sorts of deductions were made from doctors' incomes for a variety of reasons which the doctors had not foreseen. The payments for dentistry rose so precipitously that they constituted a totally unexpected drain on the costs of the service. A general practitioner is permitted to take 4,000 persons on his list; they discovered shortly that they were being overwhelmed with trivial complaints. In many instances practice has been reduced to a question and a prescription.

### SECURING EYEGLASSES

Let us see how a patient secures a pair of glasses under the National Health Service in accordance with the regulations. First, there must be a note from the family doctor that the eyes need testing. The regulations say, "Your family doctor (whether or not he himself is taking part in the service) will give you this note if he agrees that you should have your sight tested. Ask him for it." If the patient is unwilling on conscientious grounds to get a doctor's certificate, he may apply to the executive council in his area. The patient can have the sight tested either by a doctor who is known as an ophthalmic medical practitioner or by an optometrist, who is called an ophthalmic optician. A list of these persons is posted in the post office, also in the local executive council office. When the patient has decided which of the examiners he wants, he calls on him and hands him the family doctor's note. The patient must supply his national registration identity number. Then when the sight has been tested, he is requested to sign a certificate, so that the ophthalmic medical practitioner or the ophthalmic optician can obtain the fee from public funds. If the person tested is under 16 years of age, someone else has to sign for him.

Next the patient goes home and some days later receives through the mail the prescription for the glasses. He now chooses from a list of dispensing opticians in the post office one who will make the glasses. The patient then goes to the optician, who makes the necessary measurements and also tells him which type of glasses he can have without charge and when they will be ready. Here he again gives his identity number and also signs a new form, so that the optician can get money from the government. Because there is a shortage of frames, the patient is requested to bring along some frames if he has some. Anything outside the prescribed frames and glasses is paid for in a seperate payment.

If the patient loses or breaks the glasses less than two years after being tested, he can go back and get another pair but has to pay the cost himself unless he can prove that the loss or damage was not caused by his own carelessness. There is a special procedure and a number of forms involved in this phase of the service. If the patient breaks the glasses or loses them more than two years after he first got them, he has to do the whole thing over. That is an exact statement of the procedure from an official document.

The following account is of the experience of a patient who decided to get some glasses:

> I felt all the summer I needed new glasses, so at length I decided to get them. Then I found that I must first see my doctor. That meant going to his surgery, which is only open certain evenings at 6 o'clock to 6:30, waiting your turn to see him in a cold bare passage with a wooden bench to sit on. Then all he does is to sign a 3 by 1½ inch flimsy bit of paper saying that he has examined one's eyes and found that one was in need of new glasses; but he did not trouble to even look at my eyes, so the paper is a lie. Then I had to take it to an optician, who said, "Which of the two specialists would you choose to see?" I said, "Do not you test eyes?" "Oh no, we only carry out the doctor's prescription. If you come to us you must be tested by a doctor." So I chose one, and then they made an appointment for me with him after requiring to see my National Identity Card!! I've carried it about with me since 1938, and that is the first time I've been asked to show it. One week to wait for the appointment and another expensive journey to Bedford to make. The doctor took three to four minutes to look at my eyes and

---

[2] The Private Patient, editorial, M. Press **220**: 355 (Nov. 3) 1948.

put me through a few tests, another two minutes to ask my age, my full name, and my Identity Number—("show me your card"). Next, "Your doctor's certificate, please." "I haven't it. I did not know it would be required again." "Well, without it you can have no glasses. If you have lost it, you must get another from your doctor and send it to me. It has to be sent on to the Ministry for a license to be granted. Then they (the Ministry) will send you an order to procure your glasses, which you will take to your optician, who will then contact me, and I will then send your prescription to him. This will take three weeks or a month. Next the glasses will be made, which may take a further eight to twelve weeks!!! The reason for such a time being shortage of glass for the lenses. No choice of rims is given. If you don't like the ones provided, you must pay for those you do like yourself."

### OVERPRESCRIBING

One of the greatest evils of the new British Health Act is overprescribing. Thus, Dr. Harvey of Dorchester, Dorset, writes[3]:

> . . . *since July 5 I have already written in my surgery alone* 970 prescriptions, 1 per 4 patients on my list, excluding all prescriptions on my rounds, and this in the less busy summer months. One is amazed by the extras such as douches and nozzles, eye baths, pessaries, etc., one is invited to supply . . . More strange and more alarming still is the undoubted fact that the patients think they get all these extras free because the Government supplies them. I am firmly convinced that the huge cost of prescribing now piling up will in the short run return to the public for payment by increased taxation or other methods no less distasteful. The working classes will pay the largest share, as they represent the greater proportion of the population, and doctors may quite probably be compelled to pay by reduction of capitation rate as well as taxation.

Particularly serious in this performance is the bureaucratic domination of the tiniest details involved in medical care. According to the *British Medical Journal*[4]: Members of the profession complain because they cannot get clothing coupons which entitle them to purchase white coats. The government permits them to get white gowns but not white coats. They are entitled to a coupon equivalent to the purchase of six gowns or coats and to a replacement coupon for three gowns or coats. The application must, however, be made to the Ministry of Health in Scotland, and for Northern Ireland to the Secretary of the British Medical Association.

To one of the state medical licensing boards in the United States came recently a letter from a British physician which says:

> After four years of practice here I have had enough. With the event of socialized medicine, state controlled, the last vestige of freedom was taken from us. Medicine here is now pure mockery of the art and science: mass produced medicine; bottles of placebos; 50 or 60 persons per surgery session. I forecast that in a few years the doctors here will be in state of stagnation.

Particularly interesting is a bulletin from Great Britain entitled "Remuneration of Doctors Under the National Health Service," dated January 1949. A general practitioner with 2,000 persons on his list has a net income of £1,090, or about $5,000, per year. With 3,000 persons it moves up to $8,000 per year, and with 4,000 persons to almost $9,000 per year. The capitation fee varies from area to area. The bulletin tells the doctors that there are many possibilities to add considerably to their earnings within the general medical and maternity services. He might add to his earnings by mileage payments if he has to travel much in rural areas or by inducement payments, provided that he will settle in a difficult or unpopular area. In these circumstances the Minister has some extra money to distribute. He can train an assistant and get a grant for supervision, plus the salary of the assistant. He can get $21 for a maternity case for a patient on his own list, and if he has special qualifications, so that his name is entered as an obstetrician in addition to being a general practitioner, he gets $29.40 for an obstetric case. By my computation the difference here between a general practitioner and an obstetrician is $8.40 per case. If he supplies drugs to his patients or puts in dressings, he is allowed 2 shillings 6 pence per year for every hundred persons on his list, and if he dispenses drugs by an arrangement with the Executive Council, he gets a flat rate of 6 shillings 6 pence per year for each person on his list, and additional payments, provided the Executive Council agrees, for especially expensive items. Moreover, he gets extra remuneration in the form of a grant from the Hospital Management Committee if he takes care of the persons who work in the hospital. He is allowed 2.75 per cent interest on compensation money that the government still owes him. He also gets between $8 and $9 for sitting on various boards and committees, and than he is allowed fees for private patients. One doctor wrote that he still has 3 private patients.

### THE SPECIALISTS

The Spens Committee was appointed by the British government to determine the remuneration of specialists and their selection. They recommended a range of remuneration for specialists from $6,000 to $20,000 per year, but any remuneration above $10,000 a year depends on an award of special distinction made by a so-called Special Awards Committee. This committee selects the specialists who are to receive higher financial rewards than the normal rate. Thus far it is reported that only five specialists in Great Britain received the top income of $20,000 per year. Moreover, the specialists are already suffering from the difficulty of obtaining hospital beds for their patients unless they are enrolled in the service. Difficulties arise also because of the power of health councils in various areas to determine who may act as a specialist in any hospital.

The specialists may be credited, through the Royal Colleges of Physicians, Surgeons and Obstetricians, with having damaged the negotiations between the British Medical Association and the Ministry of Health by acting independently of the whole profession. On May 5, 1948, the British Medical Association decided that the profession would not refuse to cooperate in carrying out the Act, although previously a majority of the profession had voted against participation. However, the deadlock which had led the British Medical Association to advise its members to refuse to enter the scheme was broken after an exchange of letters and conferences between the presidents of the Royal Colleges and the Minister. These letters discussed the main points which disturbed the profession. Following these negotiations, the British Medical Association resumed its negotiations with the Minister. This independent action by the specialist groups unquestionably weakened the position of the British Medical Association in endeavoring to present the point of view of the medical *profession as a whole.*

[4] White Coats and Operating Gowns, Brit. M. J. (supp.) 2:82 (Aug. 14) 1948.

Under the Spens Committee proposals a national committee, predominantly professional in composition, selects the individual specialists whose outstanding distinction merits higher financial rewards. The expenses of specialists reasonably incurred in the course of work are met, and the specialists are entitled to definite holidays and extended leaves for study or research without assuming the financial liability for a substitute.

Because of the varying values of money, the 1939 values are the basis for calculation.

### THE UNIVERSITIES AND THE HEALTH SERVICE

As was stated previously, the universities and teaching hospitals were exempted from the operations of the National Health Act. Dr. J. Henry Dible,[5] Professor of Pathology of the University of London, records his experience and the change in his functions which has come about with the arrival of the National Health Act. A professor is usually appointed because of his contributions to his subject arising from original investigations, his reputation for learning and his ability as a teacher. These qualities do not develop without a large measure of free time for thought and reading and also for research. When the professor is appointed to a chair, he assumes administrative responsibility for his staff. Medical professors have, in addition, to these duties, to care for patients, establish modern clinical diagnostic tests and, if the professor is a pathologist, administer the postmortem service. These services continue throughout the year and are not lightened by long vacations. Professor Dible reports that the task has become impossible as a result of the National Health Service. "The universities," he says, "are dragged in as participants." The professors are regarded as medical specialists and therefore become servants of the hospitals and through them of the board of governors and the Ministry rather than members of a university staff. The professors are called on to sit on innumerable committees concerned with hospital administration and finance and must concern themselves with the training of the specialists of the future. He says:

> Within the past week I have received the minutes and agenda from a hospital board of governors amounting to 58 pages and papers from an educational institution amounting to 49 pages; and these represent the labours of only two of the considerable number of committees upon which circumstances are forcing me to sit. Much of this work is not in the remotest degree concerned with learning and the advancement of my subject. . . . A great deal of this material is a recent fungous growth, much of it created by individuals who have been appointed to administrative offices which are new creations, and justify their existence by busy promotion of schemes which are of questionable value.

Professor Dible mentions the Spens Report on the remuneration for clinical specialists and comments, " . . . the simple-minded consultants have, it seems, swallowed the bait, each no doubt believing in his own heart that he will be one of the favoured worthies to whom the higher rewards will go." Incidentally, the universities are alarmed because the medical professors who are qualified as clinical specialists now receive rewards far beyond those available to professors on the faculties of arts, science, law or engineering.

For himself, Professor Dible says:

> If a choice is to be made between on the one hand the large financial gains offered to hospital specialists, with which must be coupled the conditions of service under the Ministry of Health, and on the other the status and emoluments of a professor with the traditional freedom and privileges of that office, even at a much lower salary, I should not hesitate to accept the second.

Subsequent issues of the *Lancet* have brought forth many letters of agreement with the point of view of Professor Dible.

Dr. A. St. G. Huggett[6] of St. Mary's Hospital Medical School in London has emphasized the great lack of young men available to fill posts in the universities. Thirty-nine per cent (62 appointments out of 160) of available vacancies in nonclinical departments remained without any applicants. In 17 appointments, medically unqualified personnel have been put to work. Of the 81 remaining posts, to which medically qualified persons were appointed, for 30 there was only 1 applicant. He says, " . . . not enough idealists are coming forward to meet the requirements of the academic side of the profession under modern conditions." The increased needs arising out of the Spens Report, plus the postwar cost of living, is so impairing recruitment that the laboratory departments in the universities are being extinguished. Professor Huggett points out that nobody can work for more than twenty-four hours a day and that the responsibilities added by the National Health Service are in addition to the duties usually carried on by the full time teachers in the medical schools.

Professor John Grieve[7] of the Medical School, Dundee, looks with alarm on the possibility that the professors should not do clinical work. He agrees with Professor Dible that excessive administrative appointments are productive of verbiage in the form of long memorandums and reports. "Associated with this is the excessive use of standing committees," he says. The National Health Act provides for a medical education committee in addition to the medical faculties. Thus, even for the universities which have been exempted from the Act and for the denominational hospitals which have refused to serve under the Act there is no happiness in Great Britain.

Perhaps six months is too soon to judge the workings of the British National Health Act. Several of my close British friends who hold positions in the British Medical Association have urged that Americans do not comment or report on the British Health Act since it is still on trial. However, one officer of the Ministry of Health told me that it might take fifty years before the Act could be working satisfactorily, and a Scotchman suggested that a hundred years would come closer to a proper estimate.

In the *British Medical Journal*[8] is a statement by the secretary of the British Medical Association, who says, "Of the serious current problems the loss of income, often amounting to hardship, of particular groups and particular individual practitioners is perhaps the first." A committee has met with the Minister of Health and urged an increase in the mileage fund in order to deal with the problem of rural practitioners, but the action by the Minister has not become available.

---

[5] Dible, J. H.: The Universities and the Health Service, Lancet 2:861 (Nov. 27) 1948.

[6] Huggett, A. St. G.: The Universities and the Health Service, Letters to the Editor, Lancet 2:945 (Dec. 11) 1948.

[7] Grieve, J.: The Universities and the Health Service, Letters to the Editor, Lancet 2:946 (Dec. 11) 1948.

[8] Hill, L.: The Secretary Reports, Brit. M. J. (supp.) 1:43 (Jan. 1) 1949.

A second problem is the application of the Spens Report with a view to determining proper remuneration for both urban and rural practitioners and the third problem is the increase of work, particularly work of a nonmedical character. "This," says Dr. Hill, secretary of the British Medical Association, "must await the Report of the Government Certificates Committee."

Apparently the representatives of the medical profession are having trouble with the Ministry over payment for the first four days of July, over settling up the National Health insurance payments, over payments in connection with the maternity scheme. To quote Secetary Hill, "A steady but heavy pressure is being applied to the Ministry on a wide front."

Innumerable problems arise in relation to proper remuneration for a wide variety of medical service. There was, for instance, the question of payment to a surgeon which has a maximum of £75, or about $322, for an operation, but in some operations two surgeons work together, and apparently regardless of how much service is involved the £75 remains.

There is the question of filling out of the forms in relation to prenatal care and the amount of money the doctor gets if he happens to miss one examination. There is the problem of the doctor who is called to attend a miscarriage without having made previous arrangements for maternity medical service. The doctor is sometimes called when a patient bleeds after extraction of a tooth. That raises an issue between the doctor and the dentist and the question as to whether or not the money comes out of the central pool. There are high charges for use of the telephone in securing the ambulance or in getting a patient into a hospital. These complaints fill page after page of the supplement to the *British Medical Journal* and the departments of correspondence, as well as the various sections of the *Lancet*. In a recent issue of the *British Medical Journal* at least four letters appeared from doctors urging the medical profession to resign from the service.

Sir Francis Fraser,[9] Director of the British Postgraduate Medical Federation, discusses "Medicine in the New Social Order." He recognizes that there is great confusion in the operation of the National Health Act.

> "Large numbers of inspectors from the various ministries and departments, information bureaus, resettlement officers, health visitors, almoners, social workers, and so on, are being appointed to ease the difficulties of personal readjustment. Will they not suffice?"

He believes that doctors will have to concern themselves with education of the public into the new social order. "Lay officials cannot take his place." As the very latest view that I have been able to secure from England, I quote this paragraph:

> At present the general practitioner is having a bad time. He has so much to do that he is in danger of losing that joy in work well done which is essential to happiness. This is, I believe, a passing phase, and I hope that before long he will be relieved of much of the certification and paper work of all kinds which could be done as well by others, with the development of health centres and group practice, he should be relieved to an increasing extent of his present almost intolerable burdens.

## CONCLUSION

1. No doubt the time is too soon to pronounce an ultimate verdict on the effects of the British National Health Act on the health of the people of England. Nevertheless, after six months of operation of the National Health Act the statements coming from British physicians themselves indicate that there has been a deterioration in the general quality of medical service.

2. Although there is a shortage of doctors, nurses, hospitals, health centers, drugs and people trained to handle the paper work which is an excessive burden on the physician, British physicians having yielded are attempting to make the system work.

3. An organization of British physicians called the Fellowship for Freedom in Medicine, headed by Lord Horder, has undertaken a campaign to protect the freedoms of the physician. The objects of the Fellowship are:

A. To insist upon the preservation of the highest standards of medical practice.

B. To protect the public and the medical profession from state monopoly in Medicine.

C. To preserve the ethical and professional freedom of the individual doctor in the service of his patients, and to maintain the status of the general practitioner, including his financial security.

D. To oppose all encroachments by the State on the independence of medical educational institutions, and to maintain the academic freedom of all teachers of Medicine.

E. To define the limits of State Medicine so as to protect the common law rights of the public and of the medical profession in relation to all types of independent practice.

This organization feels that the British Medical Association has failed in opposing the serious infractions on the practice of medicine made by the government and in giving information to its members as to the workings of the Act. Its latest bulletin (January 1949) indicates that a vast cumbersome machinery makes it difficult for young men to get into practice.

4. A consensus of letters signed by British physicians reveals the following fundamental criticisms:

(*a*) The average man and woman feels that a cleft has been dug between him and his doctor. The doctor finds himself spending most of his time filling in forms, to the great detriment of the really sick.

(*b*) . . . because of the large list I am kept tremendously busy dealing with trivialities and form-filling, and am not therefore able to concentrate properly on doing my work to the best of my ability.

(*c*) I am the third generation in my family in this practice . . . my total mileage has been about 8,000 in six months . . . the mileage allowance is £45 ($180).

(*d*) It is now painfully obvious to the general public that the service they are getting is thoroughly . . . inferior.

(*e*) The standard of Medicine has deteriorated gradually since July.

The Fellowship for Freedom in Medicine says that only one of Dr. Dain's freedoms for the doctor guaranteed by the government has not yet been interfered with, and that is the right to speak or write about medicine or the service without hindrance.

5. Private practice in England has been reduced so that it is now nonexistent in many parts of the country.

6. There is no reason to believe that a similar system would be any more efficient or satisfactory in the United

---

[9] Fraser, F.: Medicine in the New Social Order, Lancet 1: 131 (Jan. 22) 1949.

States. Doctors simply cannot see, give diagnosis to and treat patients in a process in which they are overwhelmed by trivial complaints. If a doctor tries to see 40 patients a day, he gives all of them less than what medicine requires. If he tries to see 100 patients a day with a view to developing an income, he is reverting to the kind of diagnosis and treatment that prevailed in a previous century.

7. Inevitably the nationalization of medicine will lead into the nationalization of every phase of American life. Herbert Spencer wrote:

> The price of liberty is external vigilance. But it is far less against foreign aggression against liberty that this vigilance is required than against the insidious growth of domestic interference with personal liberty.

# Clinical Notes, Suggestions and New Instruments

## FATAL AGRANULOCYTOSIS OCCURRING DURING PROPYLTHIOURACIL THERAPY

### Report of a Case

BENJAMIN JULIAR, M.D.
Detroit
and
THOMAS L. HARRIS, M.D.
Parkersburg, W. Va.

Shortly after the use of thiouracil as an antithyroid drug became common its potentialities as a depressant of polymorphonuclear cell formation became apparent. A number of cases were reported in which this complication resulted in death. The profession was cautioned that great care be exercised in its use and that frequent blood cell counts be done during the course of therapy. The development of propylthiouracil resulted from the search for a more potent and less toxic drug.

Propylthiouracil is the only antithyroid drug listed in the 1948 edition of "New and Nonofficial Remedies." It is cautioned that this drug is capable of producing toxic reactions the severity of which is unpredictable—the most severe and serious one being agranulocytosis.

That leukopenia can occur with the use of propylthiouracil has been mentioned in a number of articles. McCullogh, Hibbs and Schneider[1] reported 1 case of granulocytopenia in 218 cases studied. Eisenmenger and Steele[2] reported a case in which pronounced leukopenia developed and thyrotoxicosis increased in severity while propylthiouracil was being administered. Livingston and Livingston[3] reported a case in which both agranulocytosis and jaundice developed. The white blood cell count fell to 1,000 cells per cubic millimeter with no granulocytes. Their patient, however, responded to the use of penicillin and the withdrawal of propylthiouracil. Bartels[4] analyzed 672 cases in which propylthiouracil was being given in preparation for thyroidectomy. Thirteen definite reactions were recorded. Significant leukopenia, granulocytopenia or both developed in 7 patients and agranulocytosis in 3.

Because of the low incidence of complications during therapy with this drug laxity has crept in. Propylthiouracil is now even being prescribed for the suppression of certain "nervous and anxiety states," giving the impression that its use is without danger and supervision can be superficial.

We believe that the case being reported here is the first instance in which agranulocytosis developed during administration of propylthiouracil, was resistant to treatment and resulted in the death of the patient.

### REPORT OF A CASE

E. J. D., a 25 year old white married woman, was seen by one of us (B. J.) on April 13, 1948. The chief complaints were nervousness, pronounced tremor of the hands and weight loss. She had felt well until December 1947, at which time she had had a spontaneous miscarriage. The bleeding incident to this was not pronounced. However, the loss of this pregnancy had upset her greatly, since she had been very anxious to have another child. In January 1948 she had a severe attack of sinusitis which necessitated paracentesis and irrigation of both maxillary sinuses. About this time, also, a disturbing marital situation arose. The patient discovered that her husband had been married previously and had not obtained a divorce from his first wife.

She began to note that she was very "nervous," would cry readily and would lose her temper at the slightest provocation. A decided tremor of the hands became apparent, and this was so severe at times that she was unable to control it and would drop whatever she was holding. Prior to the onset of the present illness her usual weight varied between 110 and 115 pounds (50 and 52 Kg.). This had declined definitely. Her appetite became poor, and there was decided diminution in her general strength.

The past history by systems elicited the following information. An appendectomy had been performed in 1942 for acute appendicitis. Tonsillectomy had been done at 6 years of age for recurrent sore throat. She had noted repeated episodes of generalized urticarial eruption and swelling of the lips when she was "nervous, tired or mentally upset." Rapid heart action had been noted during the previous three months. She also had a feeling of having to breathe fast "to catch up with herself." During the past few months she had been smoking about 20 cigarets daily and was consuming about 15 cups of coffee a day.

*Physical Examination.*—The patient was nervous appearing, fidgety and uncooperative. She cried a good deal while the history was being taken. She appeared fairly well developed, but showed definite evidence of weight loss. She was 61½ inches (156 cm.) tall and weighed 99½ pounds (45 Kg.). The temperature was 99 F.

Moderate exophthalmos, slight stare and lid lag were noted. The thyroid gland was diffusely enlarged, but more so on the right. A bruit of moderate intensity was heard over the right lobe of the thyroid. Examination of the lungs revealed no abnormalities. There was no demonstrable cardiac enlargement. The rhythm was regular; the rate was 150 per minute. No murmurs were heard. The blood pressure was 140 systolic and 70 diastolic. The muscle strength of both upper and lower extremities was definitely diminished. A fine tremor of the extended fingers was present. The results of remainder of the physical examination were essentially normal.

The basal metabolic rate was + 51 per cent. The blood cholesterol was 79 mg. per hundred cubic centimeters. The electrocardiogram was normal except for pronounced sinus tachycardia. The result of the Kahn test was negative. The urine was normal. A routine blood cell count revealed: hemoglobin 12.7 Gm. (89.4 per cent), red blood cells 5,010,000 and white blood cells 6,800, with 43 per cent polymorphonuclear cells, 50 per cent lymphocytes, 3 per cent monocytes and 4 per cent eosinophils.

The conclusion was that this patient had (1) hyperthyroidism, (2) recurrent urticaria and angioneurotic edema, (3) chronic sinusitis and (4) psychoneurosis—severe, situational. The following regimen was started: propylthiouracil, 50 mg. four times a day; phenobarbital, 30 mg. three times a day; large doses of multiple vitamins, and high caloric feedings.

The patient was next seen about two weeks later. The symptoms previously present had diminished in severity. Her weight was now 103 pounds (47 Kg.). The blood cell count was essentially unchanged from that previously given. She stated that she was returning home, to Memphis, Tenn., and a résumé of her record was sent along for transmission to her physician there.

[2] Eisenmenger, W. J., and Steele, J. M.: Leucopenia Following Use of Propylthiouracil, J. A. M. A. **135**: 510-511 (Oct. 25) 1947.

[3] Livingston, H. J., and Livingston, S. F.: Agranulocytosis and Hepatocellular Jaundice Following Use of Propylthiouracil, J. A. M. A. **135**: 422-425 (Oct. 18) 1947.

[4] Bartels, E. C.: Agranulocytosis During Propylthiouracil Therapy, Am. J. Med., **5**: 48-52 (July) 1948.

Nothing further was heard from her until August 8, when she came under the care of Dr. Harris at Parkersburg, W. Va. Her chief complaint then was sore throat of five days' duration. She stated that she had taken the propylthiouracil for only about two weeks after she left Detroit. Her physician in Memphis advised that it be discontinued. The reason for his doing so is not known. Strong iodine solution was prescribed instead. After using the latter medication for one week she noted a recurrence of all the symptoms previously complained of and propylthiouracil therapy was again started. The dosage advised is also not known. She had continued using this drug. In addition to the sore throat, she complained of fever (worse at night), recurrent chills, extreme thirst and a vesicular eruption in her mouth. Headache and blurring of vision were also noted. On her admission to the hospital in Parkersburg her temperature was 101 F.; the pulse was 90 per minute, and the respirations were 20 per minute. An extensive urticarial eruption covered most of her body. The gums were slightly swollen and tender. An oral eruption was not noted at the first examination. The lungs were clear. The heart tones were regular and of good quality.

A blood cell count done on August 9 showed: hemoglobin 12 Gm., red blood cells 4,470,000 and white blood cells 5,700, with 32 per cent segmented polymorphonuclear cells and 68 per cent lymphocytes. Results of agglutination for typhoid O and H and paratyphoid A and B organisms were all negative. The blood culture was negative.

Six hundred thousand units of duracillin® (crystalline procaine penicillin G) were given four times a day. Treatment with the usual supportive measures was instituted. In the meantime the temperature had risen to 105 F; it remained between 103.4 and 105.4 F. for the next four days. Ulcerative lesions appeared in the mouth on August 9.

In spite of the continued use of penicillin, the white blood cell count fell to 2,200 on August 10 (6 per cent polymorphonuclear cells and 94 per cent lymphocytes) and to 1,500 on August 12 (2 per cent polymorphonuclear cells and 98 per cent lymphocytes). A transfusion of whole blood was started on August 11, but this had to be discontinued after only 100 cc. had been given because of a severe reaction. The patient became delirious and irrational; jaundice became apparent, and she died on August 12. Permission to perform an autopsy was not obtained.

### COMMENT

One cannot say with certainty that the agranulocytosis which developed in this case was due to the administration of propylthiouracil. However, we believe that it is fair to assume that this drug was the most likely cause. The patient's failure to survive precluded any studies which might have been done to establish this fact. We were also unable to ascertain the dosage of propylthiouracil the patient was taking. Several letters sent to the physician whom she had consulted in Memphis were not answered. One can only conjecture about the role her past allergic history played in the reaction.

This patient showed no response to the administration of penicillin. The polymorphonuclear cells continued decreasing in spite of huge doses of penicillin. The cases of leukopenia and agranulocytosis (resulting from the use of propylthiouracil) reported in the literature showed a favorable reaction to withdrawal of the drug and administration of penicillin.

### SUMMARY AND CONCLUSION

A case of agranulocytosis, probably resulting from the use of propylthiouracil, is presented. The exact dosage taken could not be determined since the patient was not under our observation during a good deal of the time she was taking the drug. The agranulocytosis was resistant to very large doses of penicillin, and resulted in death. To our knowledge this is the first reported death from agranulocytosis occurring during the administration of propylthiouracil.

# Council on Pharmacy and Chemistry

## REPORT OF THE COUNCIL

*The Council has authorized publication of the following statement from the Therapeutic Trials Committee, a standing committee of the Council on Pharmacy and Chemistry.*

AUSTIN SMITH, M.D., *Secretary.*

## FUNDAMENTAL SCIENTIFIC RESEARCH ESSENTIAL TO PROGRESS IN APPLIED THERAPEUTICS

The Therapeutic Trials Committee of the Council on Pharmacy and Chemistry of the American Medical Association was organized especially to assist in the development and evaluation of clinical trials of therapeutic measures that require cooperative effort. The Committee, however, is keenly aware that advances in clinical therapy must be preceded by fundamental researches into the basic processes that condition life in its normal and pathologic manifestations. Without a fuller understanding of these abstruse problems, genuine advances in therapy are limited, and without such fertilization the whole field would sooner or later become virtually sterile. The Therapeutic Trials Committee therefore wishes to express its appreciation of the far-sighted wisdom of the various foundations, research councils and industrial firms and associations which, although interested primarily in special applied fields, have the vision to devote a considerable portion of their funds to fundamental research. Even though this may seem to hold little or no promise of immediate application, it is vitally essential if real advances are to be made. To make this effective requires assurance, not only of continued but of greatly increased support, in which these foundations and other organizations can be very helpful, and indeed all who are interested in advancing medical science and practice. It is a wise investment and one that is indispensable to the object of better treatment of disease, to which the Therapeutic Trials Committee is devoted.

## NEW AND NONOFFICIAL REMEDIES

*The following articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

AUSTIN SMITH, M.D., *Secretary.*

**PROTEIN HYDROLYSATES** (See THE JOURNAL, March 6, 1948, p. 693).

The following dosage form has been accepted:

WYETH, INC., PHILADELPHIA

**Lactamin *(Powder)*:** 0.45 Kg. cans. A pancreatic digest of lactalbumin containing amino acids and polypeptides equivalent to 92 per cent hydrolyzed protein providing 90 calories per 28.35 Gm. It has 50 per cent of its total nitrogen as amino nitrogen and contains no fats or carbohydrates. To be administered orally.

**INFLUENZA VIRUS VACCINE, TYPES A & B** (See THE JOURNAL, Dec. 27, 1947, p. 1153).

The following dosage form has been accepted:

ELI LILLY & CO., INDIANAPOLIS

**Influenza Virus Vaccine, Types A & B:** Packages of 1 cc. and 5 cc. vials. Preserved with Merthiolate 1 : 10,000.

**CHLORGUANIDE HYDROCHLORIDE** (See THE JOURNAL, Aug. 21, 1948, p. 1532).

The following dosage form has been accepted:

SYNTAM LABORATORIES, INC., LONG ISLAND CITY, N. Y.

**Tablets Chlorguanide Hydrochloride:** 0.1 Gm.

**DIENESTROL** (See THE JOURNAL, Nov. 22, 1947, p. 773)

The following dosage form has been accepted:

RARE CHEMICALS, INC., HARRISON, N. J.

**Aqueous Suspension Dienestrol:** 5 mg. per cc., 10 cc. vials.

## METHODS OF CASE FINDING IN TUBERCULOSIS

Although passing somewhat out of the limelight, the "tuberculin test" method of case finding still has great practical value. Under certain conditions it is the only method practicable, and it will probably continue to be useful, especially in sparsely infected regions, as long as tuberculosis remains a health problem. Notwithstanding the fact that the more recently developed miniature roentgenogram method has taken first place in effectiveness, at least in the larger and more heavily infected population centers, neither method can be used to the total exclusion of the other.

While the "practical value" of any method of case finding may be dependent on the number of cases of tuberculosis found in a given community, yet case finding, which results in the saving of lives, should not be reduced strictly to a "cost per case" basis. Furthermore, tuberculous persons vary in their danger, depending on the number of bacilli they expectorate, the number and kinds of contacts around them and many other factors. In some localities, relatively harmless cases will be found for a few dollars each, while in others, hundreds of dollars must be spent to find a dangerous case. Control of tuberculosis is similar to fire prevention and control. One cannot foretell how an unknown case of tuberculosis will behave, any more than one can foretell the outcome of a fire. Some may burn out spontaneously; others can be extinguished, while still others destroy whole areas or cities.

The facilities used in case finding have continually been improved. At first the only means of finding tuberculosis was by physical examination; then came the discovery of the bacilli and the use of the microscope, and then the roentgen ray. Following this the tuberculin test was applied with much success, and finally the miniature roentgenogram was developed.

The mass roentgenologic survey method in large communities is probably most effective and cheapest; this is true especially of the 70 mm. machine, which may be used with all the facility of the earlier developed 35 mm., and yet possesses most of the advantages of the larger (14 by 17 inch) films. The cost is not large, and the results are probably of more direct value than those obtained with any other method. The roentgenologic method finds the significant lesions which can be quickly treated.

Several things roentgenologic surveys do not do. Since roentgen shadows are not specific they are not pathognomonic of tuberculosis. Subsequent sputum analyses and tuberculin tests are necessary in 3 to 5 per cent of all cases surveyed, often revealing that conditions which at first were called tuberculosis actually are some other disease. Second, the roentgen rays will not always reveal the presence of tuberculous lesions, since about 30 per cent of the chest area is hidden, and since many early lesions do not cast shadows. Finally, the cost of mass roentgenologic surveys is not as low as the inexpensiveness of miniature roentgen film might lead one to believe. The total cost of finding an average case of tuberculosis with a good miniature x-ray apparatus ranges somewhere between $100 and $300.

The tuberculin test method, as introduced by Opie, Long, Meyers and a large number of others, has many advantages not possessed by any other technic. This method causes both laymen and physicians to become "tuberculosis conscious"—one of the first requirements of any tuberculosis program. A tuberculin test also helps to rule out nontuberculous disease. When the reaction is positive in infants and young children and even in young adults, the test is a certain indication of proximity to open tuberculosis. Because more persons will reach adult life in the future without infection the test will become increasingly useful.

One of the greatest benefits of tuberculin testing in survey work is found in communities where only 30 per cent or less of the population has a positive tuberculin reaction. Obviously the majority of the roentgenograms of those with negative tuberculin reactions would be wasted. The tuberculin method in such circumstances should be used first and followed by roentgenograms of the positive reactors. Finally, when used fully, the tuberculin test is perhaps the best index of the efficiency of a tuberculosis control program in any community.

A good example is afforded by Jordan,[1] who surveyed the schools of his district over a period of ten years. The first time he found 13.9 per cent positive reactors and the last time 4 per cent. This phenomenal decrease was attributed to several factors: First was education. Talks and demonstrations were given to students and parents, and literature on tuberculosis was disseminated. A follow-up was made by the field nursing service and roentgenograms were taken of all positive reactors; careful histories were taken and investigations of the home conditions were made. A new roentgenogram was taken of all reactors within three months to one year. Contacts were broken with all known cases of tuberculosis. Finally, the importance of a cattle-testing program to eliminate bovine tuberculosis was stressed.

---

[1] Jordan, L. S.: Summary of a Ten-Year Mantoux Program in Rural Minnesota, Journal-Lancet 62: 384-385 (Oct.) 1942.

In April of 1940 roentgenologic examination of a small school of sixty students was made. Of the 5 students who reacted to old tuberculin, 4 were examined roentgenologically. The fifth refused to have a roentgenogram taken. In April 1942 the school was retested, and of 62 in the school, 51 reacted to tuberculin. The boy who had refused roentgen examination two years before was found to have far advanced pulmonary tuberculosis, and was probably the focus of the infection.

The cost of the tuberculin method apparently includes only cost of tuberculin syringes, "hypo" needles and tuberculin. Actually the total cost is much greater. The cost per patient was estimated by Davison and Troy[2] in Chicago at something more than $500. Most of the cases were found in the high school age group or older. The number of cases in the first grade or preschool age group was one tenth that in older groups. These authors virtually condemned the method in survey work. Hewell and Nimitz[3] obtained almost identical figures in Cincinnati. However, where the number of positive reactors is small the total cost is less because the roentgenologic work is much less. The cost per case, conversely, becomes higher because fewer cases exist. The gain is then reflected in the lower death rate. Estimates of the cost depend on the number of persons surveyed and disregard the cost per case entirely; the "hidden values" cited earlier make cost accounting per case seem futile.

The tuberculin survey method is still the most practical in communities where the infection rate is low. Positive reactors may be given roentgen examinations after a tuberculin survey on entering and on leaving school. Follow-up of all contacts should be made and health education intensified.

In larger communities where the infection rate is high probably the best method is to give roentgen examinations to everybody over 15 years of age and the tuberculin test to all those with suspected lesions. Although a few small lesions will escape the roentgenologic survey, the number will not be of great importance. The cost of each method when used in its respective proper setting is probably about the same, based on the total cases surveyed. The roentgenogram is cheaper per number of cases found and number of deaths from tuberculosis, while the tuberculin test method is more useful in small communities, and is, above all, a sound index of the control of the disease. These two principal methods should and do supplement each other, the choice and sequence depending on time, place and available facilities.

## AID FOR CHRONIC ILLNESS

The American Medical Association has joined with the American Hospital Association, the American Public Health Association and the American Public Welfare Association in an Interim Commission on Chronic Illness[1] to promote programs for the control of chronic illnesses in every state. The commission is the outgrowth of recommendations from the Section on Chronic Disease of the National Health Assembly, over which Dr. James R. Miller, a member of the Board of Trustees of the American Medical Association, presided. He is chairman of the Interim Commission and will be a member of the permanent commission. About one sixth of the population of the United States has some chronic disease. At least 2,000,000 persons in the United States are at this time chronic invalids. The facilities and the methods for care of those with chronic diseases are in general inadequate in almost every section of the country. The Interim Commission has suggested the following objectives for the permanent commission:

1. To modify the attitude of society that chronic illness is hopeless; to substitute for the prevailing overconcentration on provision of institutional care a dynamic program designed to prevent chronic illness, to minimize its disabling effects and to restore its victims to a socially useful and economically productive place in the community.
2. To clarify the problems arising from chronic illness among all age groups, with full realization of its social as well as its medical aspects.
3. To coordinate separate programs for specific diseases with a general program designed to meet more effectively needs which are common to all the chronically ill regardless of the cause or causes of their illness.
4. To clarify the interrelationship of professional groups and agencies now working in the field.
5. To stimulate in every state and locality a well rounded program for the prevention and control of chronic diseases and for the care and rehabilitation of the chronically ill.

The Board of Trustees of the American Medical Association, meeting in Chicago recently, made available for the permanent Commission on Chronic Illness the sum of $25,000 and has also provided office space in the headquarters of the American Medical Association for the permanent commission, which represents the voluntary health agencies, government agencies and the public. The activities proposed for the permanent commission include:

---

[2] Davison, R., and Troy, E. P.: Experiences in Program for Control of Pulmonary Tuberculosis in Chicago, Dis. of Chest **10**: 54-59 (Jan.-Feb.) 1944.

[3] Hewell, B. A., and Nimitz, H. J.: Woodward High School Survey, Dis. of Chest **9**: 348-362 (July-Aug.) 1943.

[1] Members of the Interim Commission include Dr. James R Miller, Hartford, Conn., chairman; Dr. Thomas A. McGoldrick, Brooklyn, representing the American Medical Association; Dr. Albert Snoke, New Haven, Conn., and J. Douglas Colman, executive director, Maryland Hospital Service, Baltimore, representing the American Hospital Association; Dr. Dean W. Roberts, chief, Bureau of Medical Service, Maryland State Health Department, Baltimore, and Dr. Edward S. Rogers, of the School of Public Health, University of California, Berkeley, representing the American Public Health Association; Dr. Ellen C. Potter, Deputy Commissioner for Welfare, State Department of Institutions and Welfare, Trenton, N. J., and Judge Thomas S. J. Waxter, Domestic Relations Court, Philadelphia, representing the American Public Welfare Association.

1. To assemble existing data in order to evaluate and make use of all that is now available and to determine areas requiring further study.
2. To serve as a clearing house for information on laws, programs, experiments and new developments; to keep all interested groups informed through a newsletter published regularly, and to publish special reports from time to time.
3. To stimulate the development of new methods and technics in the organization and administration of services for the chronically ill.
4. To develop suggested patterns for integrated community programs.
5. To establish criteria for the appraisal of state and local chronic disease programs and facilities.
6. To give consultation to private and public state, regional and local agencies interested in planning for the chronically ill.
7. To suggest priorities for the determination of immediate as against long range needs for the guidance of state and local communities.
8. To explore methods of implementing the recommendations made by the commission.
9. To prepare a report to the American people outlining a comprehensive plan for the prevention and control of chronic disease and for the care and rehabilitation of the chronically ill

# Current Comment

## THE NEED FOR MEDICAL OFFICERS

The armed forces must have medical officers. A decision will be made as to whether physicians trained under the A.S.T.P. and V-12 programs who have had little or no military duty are to be drafted or will volunteer for service. An all out campaign has been started by the armed services and by the American Medical Association to obtain the 2,200 physicians needed for replacements during the remainder of this year. An equal number of A.S.T.P. and V-12 graduates will complete two years of active duty and be discharged during the same period. On page 651 of this issue of The Journal appears a statement by Secretary Forrestal. The medical officer requirements of the medical departments of the Army and Navy have been carefully scrutinized by the Armed Forces Medical Advisory Committee and are accepted by that committee as valid. Continuing study will be made to assure the minimum medical officer strength consistent with adequate services to the military forces. The American Medical Association through its Council on National Emergency Medical Service has sent a letter enclosing the names and addresses of all physicians under the age of 26 to each state medical association, urging that steps be taken immediately to appeal personally to every doctor who has not fulfilled his moral obligation to serve. The 8,000 physicians who were deferred from active military duty during World War II and trained in whole or in part at the expense of the government have a strong moral obligation to give one to two years to the government, replacing those who have already served patriotically for two years. The American medical profession voluntarily provided over 50,000 physicians to the Army and Navy during World War II. It cannot fail now to supply the demand for medical service created by the unsettled world condition. Soon the ultimate choice will be made: service on a voluntary basis or by compulsion.

## RESOLUTION ON ANIMAL EXPERIMENTATION OF AMERICAN ASSOCIATION FOR ADVANCEMENT OF SCIENCE

The American Association for the Advancement of Science at its September meeting in Washington, D. C., reemphasized its conviction that animal experimentation is essential for progress in biologic and medical sciences. Animal experimentation is considered particularly important in studies for the control of disease affecting children and for the perfection of procedures and treatments to which the nation owes a considerable part of its health and life. Animal experimentation has conferred inestimable benefits on mankind as well as on animals themselves. In view of these facts, the resolution passed by the Executive Committee of the American Association for the Advancement of Science recommends that a supply of animals for research and teaching purposes for qualified institutions be assured by legislation where necessary and not left to the option of local pound officials and private groups. A fully informed public, acquainted with the true facts of animal experimentation and the real benefits which are derived by mankind and animals generally from such work, will not support legislation which will interfere with the progress of medicine and related sciences.

## OLD AGE PENSIONS

Recently the Federal Security Agency published a release from its Chicago office to the effect that 2,300,000 persons throughout the nation are now receiving monthly payments under the Federal Social Security Program at an average monthly rate of almost $46,000,000. A simple mathematical calculation indicates that this makes an average of a little less than $20 per person. A careful study based on figures published in the *Social Security Bulletin* of November 1948 indicates that the primary benefit payable to the insured person was, in September 1948, $25.20. If the lower amounts payable to wife, child, widow or parents are calculated, the average amounts to $19.70. Since the purpose of such pensions is to care for the indispensable needs of those concerned, one wonders how they make out with either $19.70 or $25.20 to purchase food, fuel, clothing, shelter and medical and dental care.

## Official Notes

### A SIGNER RECANTS

*To the Editor:*—I am desirous of stating the fact that I signed a petition without carefully reading it and without finding out exactly how it was to be presented.

Generally, I am in accord with the policies of the American Medical Association. When I signed the foregoing mentioned petition I had no idea that the circulator of this petition would present it as a minority protest against the policies of the American Medical Association.

E. G. Wakefield, M.D.
Rochester, Minn.

### CRITICAL NEED FOR PHYSICIANS IN ARMED FORCES

The following statement, slightly condensed, was made by Secretary Forrestal at a press conference on February 25.

The armed forces are faced with a shortage of physicians and dentists which at this point is critical. Unless sufficient physicians and dentists come forward now and volunteer for service, our entire national defense program may be gravely handicapped. By July of this year we will have lost almost one-third of the physicians and dentists who are now in the armed forces. An overwhelming majority of these are former V-12 and A.S.T.P. students whose tours of duty have been completed. This new loss means that the armed forces will not have enough professional men to give necessary medical services to the almost 1,700,000 men and women who are serving their country. We are pledged to give that service, but our government will most certainly fail to do so unless we obtain sufficient professional man power. Without an adequate number of qualified medical personnel we would be helpless in the event of any unusual crisis.

There are 15,000 young physicians and dentists in America today who were deferred from the draft and excused from combat in order to complete their professional education. Of this group, 8,000 received all or part of their professional training at government expense—the remaining 7,000 paid for their own education, but were excused from the draft and combat service.

By the end of July 1949, we will be short about 1,600 physicians and about 1,160 dentists. By next December this shortage will grow to 2,200 physicians and 1,400 dentists.

We will have no one to take the place of these men other than those who are obtained through normal procurement. This method is still not sufficient to meet our needs. Last month we commissioned only thirty physicians and twenty dentists through our regular procurement channels.

We have several alternatives before us:

1. We can ask for a draft of physicians and dentists in the amount needed to provide these adequate services. We are reluctant to request this step.

2. We can ask the physicians and dentists who already have served in World War II, and who have reserve commissions, to come back into service.

3. We can issue an order which will hold some of the men now on active duty and whose service time is actually up. Neither of the latter two steps is desirable, or even fair.

4. We can ask for volunteers from the 15,000 men whom we educated as physicians and dentists and who have not served, and those who were deferred to complete their education and did not serve. I believe these 15,000 men who saw no service overseas and who were not exposed to the rigors of war will themselves recognize our right to appeal to them to make a contribution in this emergency. From the ranks of these men we should obtain the replacements for those who have served and who are now entitled to return to civilian life if they desire. In a democracy, this procedure is fair, equitable and just, and we propose to make our appeal to these former A.S.T.P. and V-12 students before taking more drastic steps.

Some of the steps which we are now taking to urge these men to discharge their duty to their country and to aid in this emergency are as follows:

1. Within the next few days, I shall write a personal letter to many of the 8,000 men who have been trained by the armed forces at the expense of the government to be physicians and dentists and who have thus far given little or no service in return. I shall invite them to accept commissions in the armed services.

2. I am appealing to the 7,000 men who were deferred and who completed their education at their own expense to volunteer and accept commissions. We are asking local professional leaders to get in touch with these men.

3. I have asked my Deputy for Medical and Allied Professional Matters, Mr. Charles P. Cooper, through the Armed Forces Medical Advisory Committee, to conduct an active campaign for medical and dental personnel. I have requested him to make simultaneously an intensive study of the utilization of this medical man power and of the workload in the armed forces in order to make certain that none of it is wasted and that, so far as possible, each of these volunteers serves in an assignment commensurate with his professional skill and ability.

4. This program is a joint undertaking of the armed forces, the American Medical Association, the American Dental Association and other allied professional groups from their national offices down to the local communities. We shall furnish these groups with the names of many of the doctors in their communities who received this government training. We shall ask them to seek out others. I shall ask them to interview these men personally and to urge on them the critical needs which face the armed forces.

5. These local professional groups will be asked to report to me as soon as possible the results of their personal contact with these young doctors.

6. I have asked the heads of the veterans' groups to assist in this campaign of enrolling physicians and dentists in the armed forces.

7. I shall ask the deans of the medical schools and the heads of hospitals to cooperate.

8. I am asking public support and understanding in this campaign to fill our needs.

Arrangements will be made by the services to allow those who volunteer at this time to finish their current training periods before being called to active duty. Calls to active duty will be staggered so as to cause minimum disruption to civilian hospital training programs.

It is our sincere hope that this campaign will succeed. If it does not, then we shall be forced to resort to more drastic means, such as holding men in the service beyond their normal time or asking Congress to pass a draft law.

We do not wish to take either of these steps, but failure in this campaign will force us to take both of them.

We have an obligation to the millions of persons concerned. These include the men and women in the armed forces themselves and the fathers and mothers of these men and women, who depend on the pledge of this government to take care of the medical needs of those who serve their nation throughout the world. They also include the citizens of the nation, who in this democracy have the right to expect that those who serve them in the armed forces will be provided with adequate medical care.

The physicians and dentists of America have always responded to such needs as now face us. We are asking them to respond again. I am sure that, if they understand the present needs, they will respond.

# Washington Letter

## WASHINGTON LETTER

*(From a Special Correspondent)*

Feb. 21, 1949.

### Medical Research Legislation Multiplying

The first six weeks of the first session, Eighty-First Congress, have witnessed an unprecedented volume of bills providing for increased federal participation in medical research. During this period, eleven bills on multiple sclerosis were filed, five on arthritis and rheumatic diseases, and one each for cerebral palsy and epilepsy. All authorize establishment of special institutes in the U. S. Public Health Service and, in their drafting, follow essentially the same formula as the national cancer and heart acts.

In addition, seven bills — most of them similar — have been introduced for creation of a National Science Foundation. Such a measure was passed by the Senate last year but the House took no action, and therefore the science foundation campaign has had to be started over from the beginning this year. Most of the House bills introduced in the present session vary from the Senate measure by providing for mandatory establishment of special federal commissions for cancer, heart disease and poliomyelitis. The Senate bill (S. 247) states simply that there shall be established "such special commissions as the Foundation may from time to time deem necessary."

### Plans for Federal Department of Welfare Advanced

Establishment of a Federal Department of Welfare moved another step toward realization on February 9 when Federal Security Administrator Oscar R. Ewing strongly urged enactment of such legislation. Giving only twenty-four hours' notice that it would conduct a public hearing on H. R. 782, the bill for conversion of the Federal Security Agency to departmental status, the House Expenditures Committee heard Ewing as the only witness on February 9. Capitol Hill observers anticipated prompt reporting of the bill to the House floor by the committee and early passage of the measure with few or no major amendments. Slower action by the Senate, however, was held probable.

In his testimony, Ewing acknowledged that professional groups have expressed opposition to combining federal health, education and social security operations in a single department, headed by a member of the President's Cabinet. They point out, he asserted, that the states generally have separate departments for these three fields, and that therefore state federal coordination would be improved if the Washington structure followed a similar pattern.

"The answer to this, I think," Ewing testified, "is that at the state and local level the activities of health, education and security are carried on by operating units whereas in the federal government these activities mainly involve research, promotion and the administration of grants-in-aid."

H. R. 782, a bill giving the Federal Security Agency cabinet status as the Department of Welfare, was ordered favorably reported to the House on February 15 by the Committee on Expenditures in the Executive Departments. Committee action on the bill, sponsored by its chairman, Representative William L. Dawson (Democrat, Illinois), followed presentation of testimony by Federal Security Administrator Oscar R. Ewing, Representatives Oren Harris (Democrat, Arkansas) and A. L. Miller (Republican, Nebraska) and representatives of the medical and dental professions.

Dr. John W. Green of Vallejo, Calif., a member of the American Medical Association House of Delegates, urged establment of a separate Department of Health rather than consolidation of health, education and social security functions in a single executive agency. At one point in the course of spirited interrogation to which he was subjected by Representatives Clare Hoffman, Chet Holifield and other committee members, Dr. Green asserted:

"If Dr. Ray Lyman Wilbur, who was Secretary of another Department some years ago, had been Secretary of a Department of Health, we would find ourselves today in a far better situation."

John Hunton, executive secretary of the California Medical Association, joined Dr. Green in replying to the congressmen's questions, which ranged in character from a definition of adequate medical care to whether blame should be attached to the medical profession if Congress enacts socialized medicine.

Opposition to H. R. 782 also was registered by Dr. Robert E. S. Young, president of the Association of American Physicians and Surgeons. "Its passage," said the Columbus (Ohio) surgeon, "would place control of the Nation's health activities in the inexperienced and unskilled hands of social or welfare workers."

Testimony by Dr. Frederick J. Quigley, past president of the New Jersey State Medical Society, was in similar vein. He stated that he has no doubt that Mr. Ewing has been propagandizing for socialized medicine.

Others heard against the bill were Dr. Henry A. Swanson of Washington, in behalf of American Dental Association, and Mrs. Marjorie Shearon. Clarence R. Miles, manager of the Department of Governmental Affairs, U. S. Chamber of Commerce, recommended that action be deferred until the Hoover Commission report on federal medical and public health functions is submitted to Congress. Witnesses in support of H. R. 782 were Mr. Ewing and John J. Corson, circulation director of *The Washington Post.*

While the committee's decision to report the bill favorably was by voice vote, and hence there was no record of the "ayes" and "nays," it was indicated that the division was strictly along party lines. A concession achieved by the Republican minority was an antipropaganda amendment of Section 1 of H. R. 782, specifying that information disseminated by the Secretary of Welfare on health matters shall be "useful and proper."

### A. M. A. Plan Gets Mixed Reaction in Washington Press

Editorial reaction to the American Medical Association's twelve point national health program was generally favorable in the Washington press. The *Evening Star* praised the Association's positive step but observed dourly that the most significant thing about the plan was the fact it was finally introduced. The *Times-Herald*, which always has been fiercely critical of compulsory sickness insurance, urged the public to give careful study to the American Medical Association proposal and the Murray-Wagner-Dingell bill, as well as the legislation which Senator Taft has said that he plans to introduce. The *Post* characterized the Association's announcement as "welcome" but one that resulted from pressure. This morning newspaper, in the past, has manifested an inclination toward federal medical insurance, but a change in position is indicated by the following excerpt from its editorial:

> Its [the American Medical Association's] emphasis is heavily on voluntary and cooperative efforts of various kinds. And this is good, both in itself and as evidence of advancing thought in the councils of the AMA. The presumption is always, or should be, that compulsion is to be avoided where possible. Not as a plague, because it is a necessary aspect of government, but as a last resort to be used only if voluntary methods have proved themselves grossly unable to perform a needed service.

### Medical Care Reviewed in Annual Report of the Veterans Administration

According to the annual report of the Veterans Administration for the year ended June 30, 1948, the most significant changes noted by the department of medicine and surgery were the increasing professional stature of medical activities, improvements in quality of care received by veterans, rising proportions of veterans discharged from hospitals on attaining maximum benefits and the declining death rate.

An all-time peak of 108,000 patients was reached during the fiscal year. The average patient load was 105,900, compared with 98,200 in the preceding year. Hospital admissions totaled 549,300 and discharges 548,000. Psychotic patients comprised almost one half the total patient load. Of the 46,500 psychotic veterans under hospitalization on May 18, 1948, 57 per cent had been hospitalized more than three years and 28 per cent more than ten years. Two thirds of them were in military service prior to World War II.

# *Medical Legislation*

## STATE LEGISLATION

### Arizona

**Bills Introduced.**—H. 153, to amend the workmen's compensation act, proposes to **accord to licensed chiropractors** equal rights and privileges with licensed practitioners of medicine and surgery by the industrial commission or any other public agency, institution, officer or employee so long as the chiropractor does not perform any act or render any service otherwise prohibited by law.

### Arkansas

**Bills Introduced.**—H. 52 proposes that any inhabitant of the state over the age of 21 years and of sound mind may, by an instrument in writing, dispose or make arrangements for the **disposition to be made of his body** or any part or organ thereof after death, provided the disposition of said body or parts thereof is made for the purpose of advancement of medical science, or for the replacement of diseased or worn out parts of other humans, or for the rehabilitation of human parts or other organs. H. 57 proposes to require **applicants for a marriage license** to present a certificate from a licensed physician of the state of Arkansas showing that a blood test of the applicant has been made and that the result of said blood test shows the applicant to be free from syphilis in the active stage. H. 236 proposes to **require the medical school** of the University of Arkansas to admit students from the various senatorial districts of the state on a basis of population of such districts. Students entering the school would be required to sign a note for $2,000 for each year of attendance, which amount would be canceled, after graduation, at the rate of $2,000 for each year the student practices in his home county. H. 240, to amend the law relating to the sale of **barbituric acid** or derivatives, proposes that sales of such drug shall be unlawful by retail pharmacies except on the written and signed prescription of a person licensed in the state to practice osteopathy as well as those entitled to practice medicine and surgery, dentistry or veterinary medicine.

**Bill Enacted.**—H. Con. Res. 4 was approved Jan. 28, 1949. It memorializes the Congress of the United States not to enact any proposed legislation the effect of which will be to bring the practice of medicine in this country under the federal direction and control, either through a form of compulsory insurance or any system of medical care designed **for national bureaucratic control.**

### California

**Bills Introduced.**—A. 1256, relating to **membership on the state board of public health**, proposes that one member thereof shall be a doctor of osteopathy, one a licensed and practicing chiropractor and four shall be licensed physicians and surgeons. A. 1697 proposes an initiative act relative to the state board of chiropractic examiners which would grant chiropractors the **right to obtain an obstetrical permit** on presentation of evidence of adequate preparation for such obstetrical practice. A. 1756, to amend the civil code, proposes to grant to private hospitals and physicians who furnish hospital or medical service to an injured person a lien for the reasonable value of such **hospital or medical service** on any cause of action for damages which the injured person may have against any other person arising out of the injury which necessitated the hospital or medical service. A. 1984 and S. 962 propose to **define a drug** as including any substance of either animal, vegetable or mineral composition or origin whose ordinary use is for the diagnosis, prevention, treatment or care of disease in man or animals. A. 2085 proposes regulations for the organization of health service groups to provide prepaid medical care and hospital service on a voluntary basis to the people of the state of California. S. 795, to amend the **business and professions code**, proposes to make it a misdemeanor for a licentiate to accept any rebate, refund, commission, preference or unearned discount in the form of money or otherwise as compensation or inducement for referring patients, clients or customers to any person, firm, association or corporation. S. 797, to amend the business and professions code, proposes, among other things, that any physician who **while practicing becomes intoxicated** to such an extent as to impair his ability to conduct the practice authorized by his certificate with safety to the public and his patients shall be guilty of a misdemeanor. S. 817, to amend the business and professions code, proposes among other things that nothing shall prohibit **the board of medical examiners** from disapproving any foreign medical school or from denying the application if, in the opinion of the board, the instruction received by the applicant or the courses were not equivalent to that required in the California provisions relating to the licensing of physicians and surgeons. S. 946, to amend the business and professions code section which now provides that corporations and other artificial legal entities have **no professional rights**, privileges or powers, proposes to add thereto the following proviso: that the Board of Medical Examiners may in its sole discretion, after such examination, investigation and documentary evidence as it may require, and under rules and regulations adopted by it, grant approval of the employment of physicians and surgeons on a salary basis by licensed charitable and eleemosynary institutions, foundations or clinics or by approved medical schools operating clinics therewith, if no charge for professional services rendered patients is made by any such institution, foundation, clinic or school. S. 947. to amend the business and professions code, proposes that the words **"diagnose" or "diagnosis"** shall include any undertaking by any method, device or procedure whatsoever and whether gratuitous or not, to ascertain or establish any fact concerning the physical, mental or nervous condition of a person. The proposal then suggests that without limiting the generality of this definition, "diagnose" and "diagnosis" shall specifically include the taking of a person's blood pressure and the use of mechanical devices or machines for the purpose of representing to any person any conclusion with respect to such person's physical, mental or nervous condition. S. 949, to amend the business and professions code relating to the **definition of the practice of medicine** and surgery, proposes to add as a part of that definition the diagnosing, treating, operating or prescribing for any physical, mental or nervous disease. S. 954, to amend the business and professions code, proposes, among other things, that before a physician's and surgeon's certificate may be issued to an applicant the applicant must show by evidence satisfactory to the board that he has received the degree of doctor of medicine from a school approved by the board and that he has completed **a year's intern training in** a hospital approved by the board. S. 966, to amend the business and professions code, proposes to eliminate the granting of a certificate to **practice midwifery.** S. 1035, to amend the education code, proposes that every attending or consulting physician who examines any child under 20 years of age found to be **totally deaf or with impaired hearing** shall report at once to the department of education the name, age, residence and the name of the parent or guardian of the minor.

### Connecticut

**Bills Introduced.**—S. 291 proposes to require any person desiring to engage in the practice of **practical nursing** to obtain a license from the local health officer of the town, city or borough in which said occupation is to be carried on. The practice of practical nursing is defined to mean practical care of the sick and is subject to direction by medical doctors and physicians, supervisors of hospitals and institutions and registered nurses. S. 331, to amend the medical practice act, proposes to eliminate from the exemption provision of the medical practice act persons practicing **the massage method and Swedish movement method.** The "Statement of Purpose" attached to the bill says: "Persons who use massage or similar methods for treatment are licensed as practitioners of the healing arts, but persons who may use such methods under the supervision of practitioners of the healing arts are licensed as physiotherapists. Masseurs are not licensed at all and cannot do therapeutic massage." S. 359, to amend the law relating to **naturopathy,** proposes to permit naturopaths to use cell salts as found in the human body, vegetable oils and nonpoisonous and nontoxic herbs in their natural state. S. 361, to amend the law relating to **premarital examinations,** proposes to permit naturopathic physicians to issue premarital blood test certificates the same as medical and osteopathic physicians. S. 363 proposes to provide representation of all schools of the healing arts in the **public health council** and to eliminate discrimination against minority schools of the healing arts. S. 453 proposes to require medical examinations by physicians licensed to practice medicine in the state, of **persons employed in the manufacture, preparation or serving of food.** The examination shall certify freedom from any contagious disease. S. 520, to amend the law relating to **annual physical examinations** of school children, proposes that such annual examination shall include a blood count and a urinalysis. S. 570 proposes that no measure relative to **birth control legislation** shall be introduced in the 1951, 1953 or 1955 sessions of the state legislature. S. 628, to amend the workmen's compensation act, proposes to permit an injured employee a **free choice of physicians.** S. 648 proposes the establishment of a **state toxicologic laboratory** for the analysis of poisons, body fluids and tissues as an aid in the detection and investigation of crime. S. 649, to amend the law relating to the **vaccination of school children,** proposes to make such vaccination mandatory rather than permissive.

### Georgia

**Bills Introduced.**—H. 155 proposes that any **applicant for a marriage license** must present a certificate signed by a qualified physician licensed to practice medicine and surgery in any state or United States territory stating that the applicant has been given an examination and that in the opinion of the examining physician the applicant is not infected with syphilis in a communicable stage. H. 589, to amend the medical practice act relating to applicants for license, proposes that the state board of medical examiners before issuing a license to any applicant who has passed the examination shall obtain from each such applicant a certificate from a hospital approved by the state board of medical examiners showing that the applicant has **completed a rotating internship** in said hospital of at least one year and that during said internship the applicant had experience in surgery, medicine, obstetrics, gynecology and pediatrics. The board of medical examiners would be authorized and empowered to approve and designate hospitals in Georgia and outside of Georgia as being satisfactory hospitals for such internship.

**Bill Enacted.**—H. 9 has become Governor's Act No. 68 of the Acts of 1949. It directs the state department of public welfare to formulate and put into effect plans and programs and facilities for the care and treatment of children residing in Georgia **suffering from cerebral palsy** and all other handicapping conditions.

### Illinois

**Bill Introduced.**—H. 110 proposes to authorize the department of registration and education to grant licenses **to practice naturopathy** under certain conditions. Naturopathy is defined by the proposal as the art and science of naturopathic medicine, which includes the diagnosis, prevention and treatment of human injuries, ailments and diseases by means of any one or more of the psychologic, physical or mechanical, chemical or material forces, or agencies of nature as taught by the accredited schools, colleges, universities or departments of universities or other institutions teaching the art and science of naturopathy.

### Indiana

**Bills Introduced.**—H. 244 proposes the creation of a **board of chiropractic examiners** and defines chiropractic as the science of locating and removing interference with nerve transmission in the spinal column. H. 350 proposes that all **children conceived by artificial means** during the period of time that the mother of such child or children was legally married, and which conception took place after the husband of such mother consented to artificial insemination, shall be deemed to be legitimate and have full rights of inheritance from both the mother and the husband of the mother who was such husband during the time that such child or children were conceived. The necessary written consent shall be witnessed by a physician holding an unlimited license to practice medicine and he shall be the same physician as the one who consummated the artificial insemination. S. 103 proposes to require every physician or oculist to report to the state board of health every person diagnosed by him as being blind or having **visual impairment** of a degree sufficient to interfere normally with such person's ability to earn a livelihood.

## Iowa

**Bills Introduced.**—H. 301 proposes the repeal of the **basic science law.** H. 380 would require the various examining boards in the state to include in their examination the **basic science subjects.** This bill is conditioned on repeal of the basic science law through the enactment of H. 301.

## Nevada

**Bills Introduced.**—A. 79, to amend the **chiropractic practice act,** proposes to eliminate from the existing law the following provision: "provided, nothing herein contained shall be construed to prohibit the use by any licensed chiropractor of all necessary electrical, mechanical, and hygienic and sanitary measures incident to the care of the body." A. 80, to amend **the chiropractic act,** proposes to define chiropractic as the adjustment of the articulations of the human body by hands or hand, and provides for the use of all necessary electrical, mechanical, hygienic and sanitary measures incident to the care of the body. A. 87 proposes that **applicants for a marriage license** shall present a certificate from a duly licensed physician, which certificate shall state that in the opinion of such physician the applicant is not infected with syphilis in a *communicable stage. S. 47 proposes certain amendments to the existing* law relating to **privileged communications.** Among other things, it is proposed that bringing of an action to recover for the death of a patient by the executor of his will or by the administrator of his estate or by the surviving spouse of the deceased or by the children personally shall constitute a consent to the testimony of any physician who attended such deceased.

## New Hampshire

**Bill Introduced.**—H. 215 proposes to require any physician or hospital superintendent to report immediately to the local board of health any person under his care or observation who is affected with a **communicable disease** or any other condition requiring reporting by the physician.

## New Jersey

**Bills Introduced.**—A. 212 proposes to require the annual **registration of osteopaths.** S. 94 proposes **to amend the medical practice act** by providing that any person shall also be regarded as practicing medicine and surgery, within the meaning of this chapter, who makes any examination, test or analysis of any fluid, excretion, secretion or tissue of the human body or of any organism contained therein, where such examination, test or analysis is made for use or is used in connection with the diagnosis or treatment of any human disease, pain, injury, deformity or physical condition or for the confirmation of such diagnosis or treatment.

## New Mexico

**Bills Introduced.**—H. 54 proposes the enactment of a **new food, drug and cosmetic act,** in which is the provision that any drug sold at retail and containing any quantity of aminopyrine, barbituric acid, cinchophen, dinitrophenol, sulfanilamide, or their derivatives, or any other drug found by the board to be dangerous shall be labeled in a certain way unless it is sold on the prescription of a member of medical, dental or veterinary profession who is licensed by law to administer such drug. H. 96 proposes to require **applicants for a marriage license** to present a certificate from a physician and surgeon duly licensed to practice medicine and surgery in New Mexico, which certificate shall state that in the opinion of such physician or surgeon the person is not infected with syphilis in a communicable stage. S. J. M. 7 would memorialize the Congress of the United States to refrain from imposing on the citizens of the nation **any form of compulsory insurance** or any system of medical care designed for national bureaucratic control. S. 65 proposes to authorize the **board of medical examiners** to grant licenses to practice medicine in the state without examination to graduates of medical colleges of either the Republic of Mexico or the Dominion of Canada if the school is accredited in such republic or dominion, if the applicant is a citizen or has applied for citizenship in the United States, if the applicant has successfully passed the required examination and, if the applicant has served an internship in a hospital within the state of New Mexico for a period of not less than two years under a reputable licensed medical practitioner.

## Ohio

**Bills Introduced.**—H. 293, to amend the medical practice act, proposes to exempt therefrom the **treatment of human ills through prayer alone** by a practitioner of the Christian Science church in accordance with the tenets and creed of such church. S. 126, to amend the provisions of the medical practice act defining unprofessional or **dishonest conduct,** proposes to include therein failure to indicate the degree held on which his certificate to practice medicine or surgery, osteopathic medicine and surgery or any of the limited branches of medicine or surgery is based when using the title "doctor" or any abbreviation thereof, on signs, cards, stationery, announcements or advertisements.

## Oklahoma

**Bill Introduced.**—S. 147, **to amend the workmen's compensation act,** proposes to authorize an injured employee to select a physician or surgeon of his own choosing.

## Rhode Island

**Bill Introduced.**—H. 678 proposes the creation of a Rhode Island **Commission for the Study of Alcoholism** to undertake a comprehensive objective study of the problems of alcoholism in the state.

## Wisconsin

**Bills Introduced.**—A. 172, to amend the **basic science act,** proposes that if an applicant fails in two or more subjects he must apply anew and stand examination in all subjects. A. 193 proposes to authorize the board of health to cooperate with the federal government and other state and community agencies in the development of programs directed toward the **prevention of rheumatic heart disease** and for the convalescent care of children with rheumatic fever, including the case finding, diagnosis and care of the acute and the convalescent stages of rheumatic fever, the prevention of recurrences and provision for such occupational therapy and subsequent care and supervision as may be deemed necessary. A. 210 proposes to require all persons licensed under chapter 147 of the Wisconsin statutes to report immediately every person diagnosed as afflicted with **epilepsy or similar disorder** characterized by lapses of consciousness. The existing statute only requires such reports by physicians. A. 213, to amend the workmen's compensation act, proposes to grant injured employees **free choice of a specialist** to care for his injuries.

---

# Coming Medical Meetings

Alabama, Medical Association of the State of, Montgomery, April 19-21. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Academy of General Practice, Cincinnati, Netherlands Plaza Hotel, March 7-9. Mr. Mac F. Cahal, 231 W. 47th St., Kansas City, Mo., Executive Secretary.

American Association for Thoracic Surgery, New Orleans, March 29-31. Dr. Brian Blades, George Washington University Hospital, Washington, D. C., Secretary.

American Association of Anatomists, Philadelphia, April 13-15. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Industrial Physicians and Surgeons, Detroit, Book-Cadillac and Statler Hotels, April 5-9. Dr. Edward C. Holmblad, 28 E. Jackson Blvd., Chicago 4, Managing Director.

American Association of Pathologists and Bacteriologists, Boston, April 15-16. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Association on Mental Deficiency, New Orleans, Hotel Roosevelt, April 27-30. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Broncho-Esophagological Association, Chicago, Drake Hotel, April 18-19. Dr. Edwin N. Broyles, 1100 N. Charles St., Baltimore 1, Secretary.

American College of Allergists, Chicago, April 14-17. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4, Secretary General.

American Industrial Hygiene Association, Detroit, Book-Cadillac and Statler Hotels, April 5-7. Dr. Henry F. Smyth Jr., 4400 Fifth Ave., Pittsburgh 13, Executive Secretary.

American Orthopsychiatric Association, Chicago, Stevens Hotel, April 4-6. Nina Ridenour, Ph.D., 25 W. 54th St., New York 19, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Hotel Waldorf-Astoria, March 4. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Physiological Society, Detroit, April 19-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary.

American Society for Experimental Pathology, Detroit, April 18-22. Dr. Frieda S. Robscheit-Robbins, 260 Crittenden Blvd., Rochester, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Detroit, April 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society for Research in Psychomatic Problems, Atlantic City, Chalfonte-Haddon Hall, April 30-May 1. Dr. Sydney G. Margolis, 714 Madison Ave., New York 24, Executive Secretary.

American Society of Biological Chemists, Detroit, April 17-22. Dr. Otto A. Bessey, 1853 W. Polk St., Chicago 12, Secretary.

American Surgical Association, St. Louis, April 20-22. Dr. Nathan Womack, University of Iowa, Iowa City, Secretary.

Arkansas Medical Society, Little Rock, April 14-16. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 1-4. Dr. H. Kenneth Scatliff, 30 N. Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 14-17. Miss Thelma Webb, 1133 Medical Arts Bldg., Dallas, Executive Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. Allan B. Phillips, 406 Sixth Ave., Des Moines 9, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 26-27. Dr. George H. Yeager, 1211 Cathedral St., Baltimore 1, Secretary.

Michigan Postgraduate Clinical Institute, Detroit, Book-Cadillac Hotel, March 23-25. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Mich., Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

New Jersey, Medical Society of, Atlantic City, Hotel Ambassador, April 25-28. Dr. Earl L. Wood, 315 W. State St., Trenton 8, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

Ohio State Medical Association, Columbus, April 19-21. Mr. Charles S. Nelson, 19 E. State St., Columbus 15, Executive Secretary.

Public Health Association, Dallas, Texas,
Dr. George A. Denison, 600 S. Twentieth
retary.

Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.

Tennessee State Medical Association, Chattanooga, April 12-14. Dr. W. M. Hardy, 706 Church Street, Nashville 3, Secretary.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## ALABAMA

**Annual Meeting of State Association.**—The Medical Association of the State of Alabama will hold its annual session in Montgomery April 19-21 at the Whitley Hotel, under the presidency of Dr. Francis M. Thigpen, Montgomery. Out-of-state speakers include:

Douglas Buchanan, Chicago, Familial Lipoid Degenerations.
Max Thorek, Chicago, The Jerome Cochran Lecture, Cholecystectomy: Its Technical Variations.
Roy H. Turner, New Orleans, Difficulties in Diagnosis Resulting from Specific Therapy.
Lawrence Reynolds, Detroit, Bronchogenic Carcinoma.
William T. Kennedy, New York, Damages in the Second Stage of Labor.
George F. Lull, Secretary and General Manager, American Medical Association, Chicago, What Does Your National Association Do for the Public?

At the Wednesday morning session recognition will be made of the Fifty-Year Club when twenty-two physicians become members.

## CONNECTICUT

**Yale Forms a Department of Microbiology.**—The Yale University Graduate School and School of Medicine are combining personnel and facilities in the formation of a new department and course of study in microbiology leading to a Ph.D. degree. This new program will include seventeen faculty members from four graduate school departments and the medical school's section of preventive medicine. The group will bring together courses now offered by the departments of bacteriology and immunology, plant science, physiologic chemistry and zoology, all under the graduate school and the section of preventive medicine. During the first year emphasis is placed on the common elements underlying the study of all forms of micro-organisms. Students will take courses in biochemistry and microbiology, including laboratory work designed to provide acquaintance with the more important types of micro-organisms. Throughout the second and subsequent years, the students devote an increasing share of their time to their major fields of interest. Familiarity with the various specialties in the general field is continued by participation in courses and seminars and through lectures and demonstrations of research by advanced students and staff members.

## FLORIDA

**New Medical Building.**—Ground was broken February 9 at the Florida Agricultural and Mechanical College, Tallahassee, for a $2,000,000 hospital, health center and nursing school building, which is reported to be the most expensive building ever constructed on a Negro college campus in the country. The event was attended by 1,500 students, educators, officials and representatives of the medical profession and dentistry. The state has authorized about $850,000, the federal government has granted about $650,000, the city of Tallahassee $250,000, the General Education Board $50,000 and the remainder was secured by private subscriptions throughout the state. The new facility will consist of a five story brick building with three hundred air-conditioned rooms and will contain a hundred bed hospital. The nursing school will admit 100 students for a four year graduate course. There will be inservice clinical training for about 50 dentists and 150 physicians. The state legislature has agreed to authorize an expenditure of $350,000 a year to meet the administrative and operating expenses of the new health center. Among those taking part in the ceremonies were Drs. Ulysses G. Dailey, Provident Hospital, Chicago; Eugene H. Dibble Jr., Tuskegee Institute, Tuskegee, Ala.; Daniel T. Rolfe, Meharry Medical College, Nashville, Tenn., and Leonard H. Foote, Florida A. and M. College, Tallahassee.

## GEORGIA

**Personal.**—Dr. J. Elliott Scarborough Jr. of Atlanta has been appointed a member of the National Advisory Cancer Council for three years to assist in formulating plans and policies of the National Cancer Institute at Bethesda, Md., and to review applications for aid in cancer control and research.

**Dr. Sheldon Named Chairman of Pathology Department.**—Dr. Walter H. Sheldon, associate professor of pathology, Emory University, Atlanta, has been appointed professor of pathology and chairman of the department. Dr. Sheldon, a graduate of the Faculty of Medicine and Surgery of the Catania Royal University, Italy, 1935, is a former instructor in pathology, Harvard Medical School, Boston, and research associate in pathology at the Boston Lying-In Hospital.

## INDIANA

**Dr. Meirowsky Joins Medical Faculty.**—Dr. Emil Meirowsky has accepted an appointment to the staff of the Indiana University School of Medicine, Bloomington–Indianapolis, as research assistant in surgery (oncology). The investigations which Dr. Meirowsky has pursued for years in his native Germany and in England are being carried on at the university. He served as professor of dermatology and syphilology at the University of Cologne for thirteen years, going to England in 1938, where he was the public health officer for Surrey County and dermatologist at the Royal Surrey County Hospital. Dr. Meirowsky's investigative work is supported by a grant from the Indiana Elks' Association through the Indiana Cancer Society.

## KENTUCKY

**Dr. Kinsman Appointed Dean.**—Dr. J. Murray Kinsman, professor of medicine and a member of the school faculty for nineteen years, has been appointed dean of the University of Louisville School of Medicine effective July 1, succeeding Dr. John W. Moore (THE JOURNAL February 19, page 534). Dr. Kinsman is president of the Jefferson County Medical Society, and a graduate of McGill University, Montreal, Canada, 1922.

**Public Health Meeting.**—The first meeting of the Kentucky Public Health Association will be held at the Brown Hotel, Louisville, March 23-25. Public health workers in Kentucky may become active members, and any one interested in public health may hold an associate membership. Sections for health officers, nurses, sanitarians, venereal disease investigators and clerks will be conducted. At the same time a school for county health officers will be held. Members of citizens health committees will also attend the meeting.

**Psychiatric Course for Social Workers.**—The psychiatric social work course of the Kent School of Social Work of the University of Louisville has been approved by the American Association of Psychiatric Social Workers. This places the university's school in a select group of seventeen accredited psychiatric social work schools in the country, only two of which are in the South. In September 1947 the program was started by means of a federal grant of $13,309 under the terms of the National Mental Health Act with Associate Professor Sylvia R. Jacobson as its director.

**Postgraduate Course on Diabetes.**—The American Academy of General Practice of Jefferson County will offer a postgraduate course in diabetes mellitus at St. Anthony's Hospital, Louisville, on Thursday from 8 to 10 p. m., April 7 through May 5. Drs. Ben H. Hollis, John D. Allen, Arthur T. Hurst, Carlisle Morse and William H. Bizot, Louisville physicians, will present lectures on subjects relating to recent advancement in the diagnosis and treatment of diabetic patients. The course is open to all physicians in Kentucky and surrounding localities. A registration fee of $10 will be charged. For information, communicate with Dr. John Rulander, 1760 Frankfort Avenue, Louisville.

## MASSACHUSETTS

**State Health Conference.**—The first annual Health Conference sponsored by the Massachusetts Department of Public Health was held in Boston February 19-20 under the chairmanship of Mr. Philip R. Mather, president of the National Health Council. The theme of the meeting was "Means of Improving Health in Massachusetts During the Next Five Years." Among the speakers were Drs. Vlado A. Getting, commissioner, Department of Public Health; John H. Cauley, commissioner, Boston Health Department; Clifton T. Perkins, Boston, commissioner, department of mental health, and Charles F. Wilinsky, Boston, president, American Public Health Association. Discussion of state health problems was carried on twenty conference panels.

## MICHIGAN

**Cancer Day.**—The Genesee County Medical Society will conduct a program on cancer April 13 at the Hurley Hospital Auditorium 9:30 to 5 o'clock. The speakers will be the following:

Arthur P. Stout, New York, Role of the Surgical Pathologist in Respect to the Cancer Problem.
Harold W. Dargeon, New York, Cancer in Children.
Thomas E. Jones, Cleveland, Cancer of the Lower Bowel.
Norman F. Miller, Ann Arbor, Mich., Management of Uterine Cancer.
E. W. Alton Ochsner, New Orleans, Basic Principles in Cancer Management.

## MINNESOTA

**Bergh Memorial Lecture.**—Dr. Andrew C. Ivy, Chicago, delivered the Luthard N. Bergh Memorial Lecture February 16 at the University of Minnesota Medical School, Minneapolis, on "Certain Aspects of the Physiology of the Extra Hepatic Biliary Tract." The lecture, sponsored by the Minnesota Medical Foundation, was made possible by gifts from relatives and friends of the late Dr. Bergh, who was on the staff of Montevideo Hospital and division surgeon for the Chicago, Milwaukee and St. Paul Railway.

## NEW YORK

**Sixth Harvey Lecture.**—Dr. Hans A. Krebs, professor of biochemistry, University of Sheffield in England, will deliver the sixth Harvey Lecture of the current series at the New York Academy of Medicine on March 17, on "Tricarboxylic Acid Cycle."

**The Program for Mental Health.**—A résumé of the state program for mental health has been published by the department of mental hygiene to meet the demand for information regarding the treatment of mental disorders. Among the innovations and improvements described are the expansion of therapeutic facilities, establishment of a much improved food service, organization of a comprehensive training program for institution personnel, extension of child guidance clinics and provision for new construction to replace obsolete buildings and relieve overcrowding.

**Postgraduate Instruction.**—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged a lecture for the Clinton County Medical Society in Champlain Valley Hospital Nurses' Home, Plattsburg, April 21, 8 p. m. Dr. William F. Lipp, Buffalo, will speak on "Diseases of the Biliary Tract Associated with Jaundice." The Utica Academy of Medicine will hear Dr. Joe W. Howland, Rochester, N. Y., speak on "Medical Aspects of the Atomic Bomb" at a meeting in the Hotel Utica in Utica March 17 at 8 p. m.

**Dedicate Psychiatric Clinic.**—A dedicatory program for *Wing R Psychiatric Clinic of Strong Memorial Hospital* and the University of Rochester School of Medicine and Dentistry will be held in the Upper Strong Auditorium of the university March 31. Visiting speakers will be the following:

Paul A. Weiss, Ph.D., Chicago, Biological Basis of Adaptation.
Homer W. Smith, Sc.D., New York, Organism and Environment: Dynamic Opposition.
Howard S. Liddell, Ph.D., New York, Adaptation of the Threshold of Intelligence.
Lawrence S. Kubie, New York, Neurotic Potential and Human Adaptation.
Clyde Kluckhohn, Ph.D., Boston, Adjustment and Adaptation: An Anthropological Approach.

### New York City

**First Brooklyn Cancer Clinic.**—The Brooklyn Cancer Committee has announced that the first free cancer detection and prevention clinic in a Brooklyn volunteer hospital is being established at the Beth-El Hospital. It will be known as the Jeri Finesilver Cancer Detection Clinic and will be devoted entirely to the treatment of those in low income groups.

**Dr. Rusk to Give Biggs Memorial Lecture.**—The Hermann M. Biggs Memorial Lecture, held annually in Hosack Hall at the New York Academy of Medicine under the auspices of the Committee on Public Health Relations, will be delivered April 7 at 8:30 p. m. by Dr. Howard A. Rusk, on "The Medical, Social and Public Health Aspects of Rehabilitation."

**Bureau of Health Education.**—Dr. George Rosen, who has been district health officer, has been named director of the Bureau of Health Education of the City of New York Department of Health. He replaces Dr. Israel Weinstein, who was director of the bureau and is now on terminal leave. Dr. Rosen is a graduate of the University of Berlin, 1935, and has been editor of the *Journal of the History of Medicine* since its beginning in 1946.

**Dr. Houssay to Give Memorial Lecture.**—Dr. Bernardo A. Houssay, Buenos Aires, Argentina, will deliver the Adam M. Miller Memorial Lecture in the Polhemus Memorial Building of the Long Island College of Medicine March 18 at 4 p. m. on "Role of the Hypophysis in Carbohydrate Metabolism and Diabetes." The lectureship, established in 1936 by the Theta Chapter of the Phi Lambda Kappa Fraternity, was created in honor of the late Adam M. Miller, professor of anatomy 1914-1935 and dean of the Long Island College of Medicine 1921-1935.

**Dr. Hawley to Give the Bampton Lectures.**—Dr. Paul R. Hawley, Chicago, chief executive officer of the Associated Medical Care Plans and former chief medical director of the U. S. Veterans Administration, will give the second series of Bampton lectures in America at Columbia University, beginning May 9, on "New Medical Discoveries and Their Effect on the Public Health." The lectures, to be given in the McMillin Theater, will be open to the public. The first three lectures, May 9, 10 and 11, will deal with "Our Fabulous Blood," blood typing, transfusions, blood substitutes and the Rh factor. On May 12 Dr. Hawley will discuss developments in heart and lung surgery. The lectures on May 16, 17 and 18 will consider the prevention and treatment of mental disease and the socioeconomic aspects of medical care. Dr. Hawley will trace the economic history of medical care and the gradual development of public responsibility in the fields of health and medical care. The Bampton lectures in America were established by the bequest of Ada Byron Bampton Tremaine.

## OHIO

**Dr. Karsner Retires at Western Reserve.**—Dr. Howard T. Karsner, professor of pathology at Western Reserve University School of Medicine since 1914 and director of the Institute of Pathology, will retire from the medical faculty at the close of the present academic year. He will then become medical research advisor to the Surgeon General of the Navy. Dr. Karsner is the author of the well known book "Human Pathology," published in six editions.

**Residency Training Program in Psychiatry.**—A three year residency training program in psychiatry will be offered in the department of neurology and psychiatry of the Ohio State University, Columbus, and the Veterans Administration Facility at Chillicothe. Quarters and subsistence will be available at the hospital for single residents. Stipends for veteran residents will be $3,300 a year and will vary from $2,400 to $3,000 for nonveteran residents. Any one interested should write to Dwight M. Palmer, M.D., department of neurology and psychiatry, Ohio State University, Columbus 10.

## PENNSYLVANIA

**Recommendation of State Society Concerning Autopsies.**—A bill to establish in the state department of health a laboratory to render proper postmortem service to coroners in various counties in their investigation of sudden or violent deaths of a suspicious nature has been recommended for presentation to the general assembly by the Committee on Public Health Legislation of the Medical Society of the State of Pennsylvania. In a recent survey the medical society discovered that in two years in thirty-seven counties there were 9,533 sudden deaths and only 594 necropsies performed to determine the cause of these deaths. In the larger counties, facilities and personnel are available for more adequate service to the coroners.

### Philadelphia

**Dr. Joslin to Give Fraternity Lecture.**—Dr. Elliott P. Joslin, professor emeritus of clinical medicine, Harvard Medical School, Boston, will discuss "The Future Diabetic" at Hahnemann Medical College April 4. This is the third annual lecture given by the Phi Delta Epsilon Fraternity. All persons interested are invited.

**Fellowship in Endocrinology.**—A fellowship in obstetric and gynecologic endocrinology will be available at the Jefferson Medical College and Hospital on or about May 1 under the direction of Dr. Abraham E. Rakoff, assistant professor of obstetrics and gynecology. The fellowship is available to doctors of medicine who have had at least one year or its equivalent of postgraduate training in obstetrics and gynecology. Applicants should communicate at once with Dr. Lewis C. Scheffey, professor of obstetrics and gynecology, Jefferson Medical College and Hospital, Philadelphia 7.

## WEST VIRGINIA

**Public Health Council Meeting.**—The spring meeting of the Public Health Council will be held at the Daniel Boone Hotel in Charleston April 7-9 for the purpose of examining applicants for licensure to practice medicine in West Virginia.

**Hospitals Licensed Since Last July.**—As the result of the new hospital licensing law, which became effective July 1, 1948, 87 hospitals and nursing homes in the state have been licensed by the State Department of Health. All institutions so licensed were inspected by representatives of the department and the state fire marshal's office. Of the original number of 179 hospitals and nursing homes, only 120 are now in existence. Applications from 28 institutions are pending, awaiting required improvements. Seventeen institutions have suspended operations, of which 8 were general hospitals, 8 nursing homes and 1 a physician's office. As 25 of the institutions had less than five beds, they do not come within the classification of a hospital. Ten were adjudged boarding houses, and 7 changed names from hospitals to another category.

Dr. Newman H. Dyer, state health commissioner, has stated that no institution will be granted a license until it has fully complied with the regulations of the state fire marshal's office. As time will be needed to provide improvements necessary to meet minimum standards set by law, every consideration will be shown these institutions until the beginning of the next licensing year. Dr. Hu C. Myers of Philippi is chairman of the seven member advisory board, which was appointed in connection with the hospital licensing program for the purpose of reviewing and approving applications for license.

## WYOMING

**Frozen Animals Unfit for Food.**—The Wyoming State Department of Public Health and the U. S. Public Health Service have issued a special bulletin to clarify the legal status of the disposition of animals which have been frozen in storm areas. Animals not properly and completely bled are subject to rapid decay from bacterial invasion. Frozen animals are dehydrated, death having been preceded by exhaustion which facilitates the penetration through intestinal walls by such bacteria as Escherichia coli, Salmonella and Staphylococcus. It is for this reason that the U. S. Bureau of Animal Industry and the State Department of Public Health have declared that meat from animals killed by means other than accepted slaughtering methods is unfit for human consumption. It is illegal to salvage any carcass, or part thereof, derived from an animal dead from freezing, for use as human food. Animals partially frozen may be presented for use as food. It requires the professional judgment of a veterinarian in order to determine the proper disposition of salvageable carcasses. Use of "Regulations Governing the Meat Inspection of the U. S. Department of Agriculture," 1947, is recommended. Further information may be obtained from the Wyoming State Department of Public Health, Cheyenne.

## GENERAL

**Society Election.**—At the annual meeting of the Western Section of the American Urological Association in Coronado, Calif., January 17-19, Dr. Arno G. Folte, San Francisco, became president and Dr. George M. Fister, Ogden, Utah, was chosen president elect and Dr. Adolph A. Kutzmann, Los Angeles, secretary-treasurer.

**Automobile Dealers Give $1,500,000 for Cancer Research.**—The Alfred P. Sloan Foundation recently received a check for $1,525,167 from 10,000 General Motors automobile dealers throughout the country. The money was collected as a tribute to Alfred P. Sloan Jr., chairman of the board of General Motors and donor of the Sloan-Kettering Institute for Research, in recognition of his efforts on their behalf. The new fund is to be set up as a separate entity, the proceeds to be distributed by grants for research.

**Clinics in Anesthesiology.**—The Committee on Education of the New England Society of Anesthesiologists will hold all day clinics for physicians doing part time anesthesia and desiring like instruction in this field of medicine. The first will be held April 2 at the Rhode Island Hospital, Providence, under the direction of Dr. Meyer Saklad. The morning session will be devoted to clinical demonstrations and the afternoon to "Anoxia and Inhalation Therapy." On May 7 operative clinics will be held at the St. Francis Hospital, Hartford, Conn., under the direction of Dr. Stevens J. Martin. Lectures will be held in the afternoon. Sessions will begin at 8 a. m. Any physician may attend by making reservations in writing to the respective directors.

**Magazine Subscription Racket.**—The Prairie Farmer Protective Union has reported a midwest racket in which a solicitor posing as a young doctor promises to establish an office and start practice in a community if given enough magazine subscriptions. In all reported incidents so far the solicitor has said he is just out of medical college and does not have enough money to set up an office. An organization about which he is vague would outfit his office if he could get enough "points," which, he explains, are determined by the number of magazines he sells. An investigation has shown that none of the communities that contributed to these subscription racketeers has secured a doctor as promised. Anyone knowing the whereabouts of the operators would be performing a public service if he will notify the Prairie Farmer Protective Union, 1230 Washington Boulevard, Chicago 7.

**Annual Meeting on Industrial Medicine.**—The American Association of Industrial Physicians and Surgeons will hold its annual meeting April 5-9 at the Book-Cadillac and Statler hotels, Detroit. Among the speakers will be Dr. Trevor A. Lloyd Davies, Nottingham, England, who will speak on "Pneumonitis as It Affects the Industrial Worker," and Dr. Gunnar Fischer, Stockholm, Sweden, "Industrial Medicine in Sweden." Seven physicians will participate in a symposium on cariovascular disease in business and industrial employment on Wednesday morning. Plant tours will be arranged for delegates and members. Other industrial health associations meeting at this time are the American Conference of Governmental Industrial Hygienists, April 2-5; American Industrial Hygiene Association, April 5-7; American Association of Industrial Dentists, April 6-7, and the American Association of Industrial Nurses, Inc., April 5-9.

**Anniversary of Red Cross Nursing Service.**—The eighty-seventh birthday anniversary on March 12 of the late Jane A. Delano, founder of the American Red Cross Nursing Service, will be observed by the stepping up of Red Cross chapter effort throughout the country toward nurse enrolment for peacetime community service as well as preparedness for possible emergency. The new Red Cross chapter enrolment program, inaugurated a year ago, is designed to help meet community health needs by providing nurses with opportunity for "plus" service through established Red Cross programs such as home nursing, nurse's aide instruction, preparedness against disaster and the National Blood Program. To date, more than 1,276 nurses have been reported as enrolled under this plan. Many previously enrolled nurses also are participating in these programs. Miss Delano became chairman of the first national committee on Red Cross Nursing Service in 1909, when she was also superintendent of the Army Nurse Corps. In 1912 she resigned to devote full time as a volunteer in building up the Red Cross Nursing Service. Under her direction the Red Cross program in elementary hygiene and home care of the sick, taught by professional nurses, was begun in 1908. A course in home dietetics followed, and in 1912 the Red Sross Town and Country Nursing Service, forerunner of modern rural public health nursing, was established.

## FOREIGN

**United Nations Plans Health Studies.**—The United Nations World Health Organization will send teams of technical experts into four countries to undertake a special program of disease control, according to the *New York Times*. One mission will go to Pakistan to advise on malaria control; a second will go to Turkey and Egypt to carry out venereal disease control, and a third to Egypt and Pakistan to study antituberculosis programs. A special team is being sent to Ethiopia for sanitation studies and other public health work. The health agency, it is reported, will provide thirty fellowships to doctors and public health specialists in all four countries and in Iran.

**British Health and Tuberculosis Conference.**—The Commonwealth and Empire Health and Tuberculosis Conference, sponsored by the National Association for the Prevention of Tuberculosis, will be held in Central Hall, Westminster, London, July 5-8. Subjects under discussion will be tuberculosis as a world problem; modern trends in its treatment; organization of comprehensive tuberculosis schemes in the colonies, regional, county and county buroughs; problems of prevention and detection; BCG administration; rehabilitation of chronic disease and protection from bovine infection. The fee is 3 pounds 3 shillings for four days, or 1 pound 1 shilling per single day or session. The conference is open to all interested in preventive medicine, including doctors, industrial executives, nurses, social workers and public health authorities.

---

# Marriages

John Alfred Emmert, Danville, Va., to Miss Olive Ann Gray of Hasbrouck Heights, N. J., November 6.

Peter F. Lansing, Peaks Island, Me., to Miss Carolyn Osgood of Wollaston, Mass., November 27.

John A. Griffin, Allentown, Pa., to Miss Emma Marie Ferry of Alburtis, R. I., November 20.

Rodney Ham Foss, Portland, Maine, to Miss Mary Louisa Roney of Cape Elizabeth, December 11.

James Craig Joyner to Miss Lucie Burke Alcott, both of New York, November 10.

# Deaths

**George Henry Hansmann** ⊕ Milwaukee; born in Manson, Ia., March 6, 1890; State University of Iowa College of Medicine, Iowa City, 1918; specialist certified by the American Board of Pathology, Inc.; member of the American Association of Pathologists and Bacteriologists and the Society for Experimental Biology and Medicine; at one time instructor in pathology at the Harvard Medical School in Boston, assistant professor of pathology and bacteriology at his alma mater, where he was chairman of the department, and associate professor of pathology at the Georgetown University School of Medicine in Washington, D. C.; formerly pathologist at the University Hospitals in Iowa City; served on the staffs of the Columbia and Milwaukee Children's hospitals; died in January, aged 58, of acute heart failure.

**Leo Samson Schwartz** ⊕ Brooklyn; Cornell University Medical College, New York, 1908; also a graduate in pharmacy; formerly on the faculty of the Long Island College of Medicine; fellow of the American College of Surgeons; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; past president of the Medical Society of the County of Kings and the Brooklyn Gynecological Society; served on the staffs of the Israel-Zion Hospital and the Jewish Hospital, where he died December 31, aged 66, of cholelithiasis and postoperative circulatory collapse.

**William Joseph Tracey,** Norwalk, Conn.; University of the City of New York Medical Department, 1889; member of the American Medical Association; fellow of the American College of Surgeons; past president of the Fairfield County Medical Society and Norwalk Medical Society; first health officer in Norwalk and South Norwalk; for many years chairman of the board of education; a public school named in his honor; life member of the board of directors of the Norwalk Hospital, where he was on the staff; died December 17, aged 82.

**Edith Loeber Ballard** ⊕ Bay St. Louis, Miss.; Cornell University Medical College, New York, 1905; member of the American Medical Association and the Louisiana State Medical Society; died in New Orleans December 23, aged 73, of adenocarcinoma of the colon with metastases.

**Clara Knauff Bartlett** ⊕ Atlantic City, N. J.; National University Medical Department, Washington, D. C., 1899; Woman's Medical College of Pennsylvania, Philadelphia, 1900; an Associate Fellow of the American Medical Association; for many years school medical inspector; died December 15, aged 81, of heart disease.

**Robert Burns Barton** ⊕ Wellesley, Mass.; Boston University School of Medicine, 1926; died November 30, aged 48.

**Howard H. Beane,** Cleveland; Cleveland Medical College, Homeopathic, 1896; died December 9, aged 74, of cardiovascular disease.

**Norman Madrid Beatty** ⊕ Indianapolis; Indiana University School of Medicine, Indianapolis, 1927; member of the American Academy of Dermatology and Syphilology; died December 5, aged 46.

**William Truman Bennie** ⊕ Shaker Heights, Ohio; Indiana University School of Medicine, Indianapolis, 1927; died January 1, aged 45.

**Willoughby Dayton Bishop,** Greenville, Ohio; Starling-Ohio Medical College, Columbus, 1913; member of the American Medical Association; for many years secretary-treasurer of the Darke County Medical Society, of which he had been president, and the Ohio Federation of Public Health Officials; served during World War I; formerly city and county health officer; died December 7, aged 58, of uremia following cerebral hemorrhage.

**Charles Elliott BoDine,** Bangor, Me.; Tufts College Medical School, Boston, 1935; member of the American Medical Association; formerly resident in obstetrics and gynecology at the Carney Hospital in Boston; interned at the Eastern Maine General Hospital, where he was a member of the staff; served during World War II; died in Brewer, December 29, aged 42, of myocardial infarction.

**Martin Laurence Bodkin** ⊕ Brooklyn; College of Physicians and Surgeons, medical department of Columbia College, New York, 1894; fellow of the American College of Surgeons; on the staffs of the Caledonian, Midwood and St. Catherine's hospitals; died December 1, aged 79, of coronary occlusion.

**Thomas Toxey Box,** Fairfield, Ala.; Chicago College of Medicine and Surgery, 1916; served in France during World War I; member of the American Medical Association; at one time health officer of Washington, Winston and Choctaw Counties; served on the staff of the Employees' Hospital of Tennessee Coal, Iron and Railway Company, where he died December 2, aged 59, of a ruptured appendix and pulmonary embolism.

**Frederick Elmer Braucht,** Elkader, Iowa; Rush Medical College, Chicago, 1894; member of the American Medical Association; served during World War I; died December 4, aged 80, of angina pectoris.

**Andrew D. Bridges,** Portland, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1890; died in Gashland, December 26, aged 93, of pneumonia.

**Harry Brown Britton** ⊕ Ypsilanti, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; past president of the Washtenaw County Medical Society; served in France during World War I; assistant flight surgeon at the Willow Run Bomber Plant during World War II; formerly health officer; died January 7, aged 74, of carcinoma.

**Harry Clinton Brown,** Stockton, Kan.; Central Medical College of St. Joseph, Mo., 1905; member of the American Medical Association; for many years county health officer; died December 19, aged 74, of cerebral embolism.

**Rudolph H. Brown,** Centralia, Ill.; St. Louis College of Physicians and Surgeons, 1902; member of the American Medical Association; died in St. Mary's Hospital January 10, aged 69, of cerebral hemorrhage, arteriosclerosis and nephritis.

**Rollin H. Bunch,** Muncie, Ind.; American College of Medicine and Surgery, Chicago, 1904; member of the American Medical Association; served as mayor of Muncie; died December 9, aged 66, of coronary thrombosis and myocardial infarction.

**Frank Burzynski,** Chicopee, Mass.; Kansas City (Mo.) University of Physicians and Surgeons, 1924; died in the Mercy Hospital, Springfield, December 18, aged 62, of chronic rheumatic heart disease.

**Frank Ernest Butler** ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1916; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; served overseas during World War I; for many years affiliated with the Emanuel Hospital, where he died January 5, aged 60.

**Rupert Butler,** Springhill, La.; Memphis (Tenn.) Hospital Medical College, 1905; member of the American Medical Association; died December 3, aged 70.

**Louis Bernard Castell** ⊕ Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1912; also a graduate in pharmacy; at one time associated with the Indian Service; served on the faculty of Georgetown and George Washington universities; affiliated with Providence Hospital; died December 22, aged 65.

**Milton Hughes Christie,** Unity, Md.; Medical Department of the University of Wooster, Cleveland, 1891; died January 9, aged 90, of coronary occlusion.

**Haynsworth Dowling Clark,** Fort Pierce, Fla.; University of Maryland School of Medicine, Baltimore, 1914; member of the American Medical Association; past president of the Florida Railway Surgeons Association and the St. Lucie-Okeechobee-Indian River-Martin Counties Medical Society; affiliated with the Fort Pierce Memorial Hospital, where he died January 15, aged 56, of coronary thrombosis.

**Lambert B. Coblentz** ⊕ San Francisco; Cooper Medical College, San Francisco, 1904; specialist certified by the American Board of Internal Medicine; clinical instructor in medicine, emeritus, at the Stanford University School of Medicine; served during World War I; affiliated with Mount Zion, St. Luke's and the Stanford University hospitals; died January 29, aged 68, of coronary thrombosis.

**Everett Monroe Cooley,** Lawrenceville, Ill.; Kentucky School of Medicine, Louisville, 1892; served during World War I; died January 6, aged 79, of diabetes mellitus.

**Chester Charles Cott** ⊕ Buffalo; University of Buffalo School of Medicine, 1908; clinical professor emeritus of otolaryngology at his alma mater; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; affiliated with the Buffalo General Hospital and the Edward J. Meyer Memorial Hospital; died December 4, aged 65, of carcinoma of the stomach.

**Alexander E. Dalton,** Cape Girardeau, Mo.; St. Louis College of Physicians and Surgeons, 1896; served as a member of the city board of health; affiliated with St. Francis Hospital, where he died December 16, aged 84, of heart disease.

**Edward John Davin,** New York; Columbia University College of Physicians and Surgeons, New York, 1912; formerly on the faculty of New York Polyclinic Medical School and Hospital; member of the American Medical Association; specialist certified by the American Board of Obstetrics and Gynecology; served during World War I and a short time during World War II; affiliated with Misericordia, Lincoln and St. Clare's hospitals; died December 5, aged 59.

**Joshua Judson Davis,** Smyrna, N. C.; University of Maryland School of Medicine, Baltimore, 1891; died in the Duke Hospital, Durham, January 15, aged 80, while undergoing an operation for carcinoma.

**Percy Joseph Delano** ⊕ Oak Park, Ill.; University of Illinois College of Medicine, Chicago, 1927; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; affiliated with the West Suburban Hospital; died in Chicago, January 13, aged 49, of burns received in a fire.

**James Thomas Doster Jr.** ⊕ Columbus, Miss.; Jefferson Medical College of Philadelphia, 1926; fellow of the American College of Surgeons; formerly owner of a hospital bearing his name; died January 1, aged 45, of heart disease.

**Fred James Douglas** ⊕ Utica, N. Y.; Dartmouth Medical School, Hanover, N. H., 1894; fellow of the American College of Surgeons; for many years member of the House of Representatives; formerly member of the city board of education, city health officer, commissioner of safety and mayor of Utica; on the staff of Faxton Hospital; consulting surgeon at Utica State and St. Elizabeth hospitals; died January 1, aged 79, of carcinoma of the rectum.

**John Edward Ellis** ⊕ West Point, Miss.; Memphis (Tenn.) Hospital Medical College, 1908; served as health officer of Clayton County; died January 4, aged 63, of heart disease.

**Victor Jacob Fingar,** West Ghent, N. Y.; Albany (N. Y.) Medical College, 1932; an assistant medical director of the Equitable Life Assurance Society of the United States in New York; served during World War II; died January 10, aged 41, of glioma of the brain.

**Harry William Fink** ⊕ Chicago; Rush Medical College, Chicago, 1921; died in Big Springs, Texas, January 2, aged 53, of cerebral hemorrhage and hypertension.

**Samuel Edgar Finley,** Brooklyn; University of Pennsylvania Department of Medicine, Philadelphia, 1893; died December 7, aged 79.

**James Thomas Fulkerson,** Stark City, Mo.; (licensed in Missouri in 1905); died December 11, aged 70, of cerebral hemorrhage.

**George Mason Graham,** Bessmay, Texas; Kentucky University Medical Department, Louisville, 1903; member of the American Medical Association; died December 21, aged 68, of carcinoma of the spine.

**James W. Griffin,** Lewisport, Ky.; Kentucky School of Medicine, Louisville, 1893; died November 21, aged 79, of leukemia.

**Henry Claude Guerin,** Nashville, Tenn.; University of Nashville Medical Department, 1905; member of the American Medical Association; died December 4, aged 71, of cerebral hemorrhage.

**Arthur Haim** ⊕ San Francisco; Hamburgische Universität Medizinische Fakultät, Hamburg, Germany, 1923; member of the Society of American Bacteriologists; formerly on the faculty of the University of California Medical School; served on the staffs of the University of California and Mount Zion hospitals; died recently, aged 50.

**James Elzie Harden,** Whigham, Ga.; University of Nashville (Tenn.) Medical Department, 1908; died December 9, aged 66, of carcinomatosis.

**Joseph F. Haselden,** Greelyville, S. C.; Maryland Medical College, Baltimore, 1904; died December 18, aged 79.

**Edwin Henry Hayman,** Ocean City, Md.; Jefferson Medical College of Philadelphia, 1899; formerly affiliated with the Veterans Administration Facility in Mountain Home, Tenn.; died December 23, aged 80, of coronary thrombosis.

**John Henry Hennies,** Brunswick, Ga.; International Medical Missionary College and Training School for Nurses, Atlanta, 1906; died December 4, aged 68, of heart disease.

**Donald Warner Herman** ⊕ Winsted, Conn.; Columbia University College of Physicians and Surgeons, New York, 1924; served as health officer; on the staff of the Litchfield County Hospital; died in the Hartford (Conn.) Hospital December 15, aged 49, following a cholecystectomy.

**Noah Sherman Hilty,** Bluffton, Ohio; Detroit Homeopathic College, 1904; formerly practiced in Pandora, where he served as mayor and as president of the board of education; died recently, aged 71, of diabetes mellitus and heart disease.

**Alfred Hoff** ⊕ St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1910; clinical associate professor of medicine at his alma mater; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the board of trustees of St. Luke's Hospital; affiliated with the Ancker Hospital; died recently, aged 65, of heart disease.

**Victor Helmer Horning,** Chicago; Bennett Medical College, Chicago, 1912; member of the American Medical Association; a captain in the medical corps, Army of the United States, during World War II; for many years assistant chief surgeon for the Chicago and Northwestern Railroad; died in the Garfield Park Community Hospital December 3, aged 66, of acute myocardial infarction.

**Gideon Lyman Howell,** Trucksville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the American Medical Association; served on the school board; for many years affiliated with Nesbitt Memorial Hospital, Kingston; died January 13, aged 63, of coronary heart disease.

**John Danes Hubbard,** Cranston, R. I.; Hahnemann Medical College and Hospital of Philadelphia, 1933; member of the American Medical Association; fellow of the American College of Surgeons; medical examiner for Cranston; served during World War II; affiliated with the Roger Williams General Hospital, Providence, where he died December 9, aged 41, of acute coronary thrombosis.

**Ellis William Jones** ⊕ Los Angeles; Harvard Medical School, Boston, 1911; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served on the staff of Cedars of Lebanon Hospital and the Hospital of the Good Samaritan, where he died December 4, aged 63, of pneumonia.

**Leonard Kawasaki,** Cincinnati; University of Cincinnati College of Medicine, 1929; member of the American Medical Association; died December 28, aged 45.

**William Edwin Keller,** Scranton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; member of the American Medical Association; died in the Moses Taylor Hospital December 29, aged 76, of arteriosclerotic nephritis.

**Frank Edward Kiesler** ⊕ Chicago; Loyola University School of Medicine, Chicago, 1921; affiliated with St. Elizabeth Hospital, where he died December 8, aged 57, of gastric hemorrhage and duodenal ulcer.

**Archie Percival Kimball** ⊕ San Diego, Calif.; John A. Creighton Medical College, Omaha, 1908; fellow of the American College of Surgeons; formerly on the staff of the Yuma County General Hospital in Yuma, Ariz.; died December 1, aged 63, of carcinoma of the right ureter with widespread metastasis.

**James Charles Elliott King,** La Mesa, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1886; Chicago Medical College, 1890; emeritus professor of dermatology at the University of Oregon Medical School, Portland; specialist certified by the American Board of Dermatology and Syphilology; member of the House of Delegates of the American Medical Association in 1902; died in San Diego, December 25, aged 87, of uremia.

**Victor K. Knapp,** Nevada, Ohio; Medical College of Ohio, Cincinnati, 1896; died recently, aged 78, of heart disease.

**Henry Edward Kock,** Cincinnati; Cincinnati College of Medicine and Surgery, 1902; also a lawyer; died in the Christ Hospital December 23, aged 71, of carcinoma of the bladder with metastasis.

**Dwight Gregor Kreul** ⊕ Davenport, Iowa; Milwaukee Medical College, 1897; affiliated with Mercy and St. Luke's hospitals; died December 18, aged 78, of heart disease.

**George Winlock Lee,** Los Angeles; Medical College of Indiana, Indianapolis, 1904; an officer overseas during World War I; at various times on the staffs of Veterans Administration hospitals in different locations; died December 15, aged 72.

**William Arthur Lee** ⊕ Denison, Texas; University of Texas School of Medicine, Galveston, 1906; chairman of the board of directors of the Madonna Hospital, where he died December 20, aged 67, of coronary thrombosis.

patient. In his circular the Minister points out that outpatient treatment has often been given in the past because the patient had no family doctor. Under the National Health Service this should no longer occur. No patient should continue as an outpatient if his case is suitable for treatment by a general practitioner. The only exceptions should be emergency cases, patients who need specialist supervision over a period and those under treatment for venereal diseases or whose attendance is desirable for medical teaching or research.

To reduce waiting time the Minister suggests the introduction of an appointment system, which should be regularly reviewed and for which the cooperation of all the staff concerned must be secured. Times of clinics should meet local circumstances, such as early closing day and times of bus services. Evening treatment sessions should be arranged so that working time need not be unnecessarily lost by patients. For the comfort of the patients the Minister calls for canteens, cheap but comfortable chairs instead of unsightly and uncomfortable forms, and cleaned and redecorated premises.

## BRAZIL

*(From Our Regular Correspondent)*

Rio de Janeiro, Jan. 23, 1948.

### Mortality from Communicable Diseases

The Statistical Division of the National Department of Health has released provisional information about the mortality from communicable diseases for the period January to October of this year for a group of twenty cities of Brazil, representing all but one of the twenty states and the Federal District (city of Rio de Janeiro).

*Tuberculosis is by far the deadliest communicable disease*, with the annual death rate of 246 per hundred thousand population for the whole sample of urban population, the individual cities ranging from 78 per hundred thousand, for Cuiabá in the central tropical region of the country to 468 and 477, respectively, for Salvador, state of Bahia, and Victoria, state of Espirito Santo, both in the tropical middle Atlantic coast. The two largest cities, Rio de Janeiro and São Paulo, present the tuberculosis death rates of 299 and 110, respectively, the difference being ascribable to the cooler climate, larger percentage of white population and higher average of economic condition in the latter city.

Next to tuberculosis comes malaria, with the annual death rate of 18.4 per hundred thousand for the whole aggregate of urban population, the individual cities varying from zero or very low death rates for the cities in the cooler Southern part of the country (average death rate of 2.5 per hundred thousand) to high death rates for the equatorial Amazon valley (Manaos 197, and Belem 186 per hundred thousand).

Dysentery (about 80 per cent bacillary) ranks third, with the death rate of 12.5 per hundred thousand for the whole group, ranging from 3.9 per hundred thousand for Rio de Janeiro to 31.6, 55.0 and 83.7 per hundred thousand, respectively, for Fortaleza, São Luis and Maceió in Northern Brazil.

Whooping cough, typhoid and diphtheria, with annual death rates of 9.1, 7.7 and 4.4 per hundred thousand, respectively, for the aggregate of twenty cities, have a narrow range of variation from city to city, the rates for Rio de Janeiro and São Paulo being 9.7 and 7.0 per hundred thousand, respectively, for whooping cough, 9.6 and 3.4 for typhoid, and 4.0 and 2.8 for diphtheria. Smallpox, poliomyelitis, epidemic encephalitis and rabies are comparatively minor causes of death, with annual death rates of 0.3, 0.3, 0.1 and 0.3 per hundred thousand, respectively. Endemic typhus is confined within the state of São Paulo, which is a focus of a particular type of the disease. The annual death rate from this disease, for the city of São Paulo, is 0.6 per hundred thousand.

## ITALY

*(From Our Regular Correspondent)*

Dec. 20, 1948.

### Society of Internal Medicine

In the historic palace of Archiginnasio at Bologna, the Italian Society of Internal Medicine heard reports on three subjects: pain associated with visceral disturbances, hemoplasmopathies and cephalea.

### Visceral Pain

Prof. Lunedei, the University of Firenze, presented a report on visceral pain for the Society of Internal Medicine; Prof. Giovanni Paroli, the University of Perugia, for the Society of Obstetrics and Gynecology, and Prof. A. Comolli, the University of Florence, for the Italian Society of Surgeons. Instead of the old classification of visceral pain into splanchnic and somatic pain, Prof. Lunedei suggested a more complete classification. He distinguished visceral pain of "deep type" from visceral pain of "superficial type."

Prof. Giovanni Paroli, Perugia, reported his studies on pain in the genital organs of women. He considered pain of the adnexa, pain of the body of the uterus and pain of the cervix. One may effectuate an exact distinction between these three deep localizations through the radiation of the pain becoming fixed at the height of the vertebral zone. The speaker then discussed the various methods of anesthesia during delivery and particularly caudal anesthesia using an oily vehicle.

Prof. Gasbarrini, rector of the University of Bologna, Alessandrini, Bacialli, Lelli-Mami, Casati and many others participated in the discussion.

### The Hemoplasmopathies

Professors Cesa-Bianchi and Poli, both of the University of Milan, presented reports on the pathology and symptomatology of hemoplasmopathies. This means the biologic and biochemic manifestations resulting from alteration of the protein constitution of the blood. Poli discussed the laboratory procedures by which these manifestations may be ascertained, and from the clinical point of view the consequences for which these manifestations may be responsible. He distinguished between primary and secondary hemoplasmopathies. The secondary he divided into "typical" forms such as may be observed in plasmocytoma, leishmaniasis, lymphogranuloma inguinale, benign granuloma of Besnier-Boeck-Schumann and measles. The speaker emphasized that "lipid nephrosis" is not a renal disease, but a hemoplasmopathy, a disease of the plasma in which the kidney participates. This participation of the kidney first remains insignificant, but successively the continuous impregnation of the glomeruli with filtrating protein material may produce phenomena of glomerulonephrosis which are capable of causing glomerular insufficiency. Professors Villa, Fanutti, Travia, Sotgiu, Sega, Melli, Puddu, Baserga, Coppo and Dominici Frada participated in the discussion of this subject.

### The Cephaleas

Prof. E. Greppi of the University of Florence was the speaker on the third subject of the Congress. He distinguished ten *clinical forms of cephaleas*: (1) psychogenic (hysteria); (2) diencephalic or central; (3) serous meningitic or hydrocephalic; (4) cephalea due to rhinosinusitis or (5) due to hyposthenic vasoneurosis (cranial neurosis) or (6) due to hypersthenic vasoneuroses (plethoric states) or (7) due to arterial hypertension; (8) hemicrania due to osteoperiosteal productive craniopathies (hyperostotic endocraniosis, Paget's disease) or (9) due to paracranial myopathia or (10) due to suboccipital myositis and fibrositis.

For every type of cephalea the speaker gave the pathogenic interpretation and the treatment. Professors Belloni, Lunedei, Melli, Mariani and Sabatini participated in the discussion of the subject.

# Medical Motion Pictures

## FILM REVIEWS

The following are a series of **Filmstrips** prepared by the Department of Rehabilitation and Physical Medicine of New York University College of Medicine, New York. Procurable on purchase from Filmstrips Inc., 1307 Sixth Avenue, New York.

**I. Crutch Exercises**, no. 101, deals with crutch exercises. It explains the necessity for preliminary bed and mat exercises and shows in detail the six key exercises which are used with the patient standing on crutches close to a wall. A group of exercises performed away from the wall are shown, and it is pointed out that these exercises must be mastered before actual crutch walking is attempted.

**II. Crutch Walking: The Four Point Gaits**, no. 102, shows in detail the simple four point gait and the four point alternate gait.

**III. Crutch Walking: The Tripod Gaits**, no. 103, illustrates the tripod alternate gait, the tripod simultaneous gait, the swing to gait and the swing through gait.

These filmstrips show an actual patient performing each step in the exercise or gait which is described and at the same time show a written description of each step. They will be especially valuable for use in any department of physical medicine or in any rehabilitation center for training patients visually in the art of crutch walking. These filmstrips are highly recommended and should be a part of the armamentarium of every center where crutch walking is being taught.

**Pentothal Sodium in Obstetrics.** 16 mm., color, silent, 1,073 feet (1 reel), showing time thirty-four minutes. Prepared in 1947 by Louis M. Hellman, M.D., Associate Professor of Obstetrics, Johns Hopkins University Medical School, Baltimore. Produced by Mervin LaRue, Inc., Chicago. Procurable on loan from: Abbott Laboratories, North Chicago, Ill.

The essential aims in achieving satisfactory obstetrical anesthesia are presented. A summary of over 3,000 deliveries is illustrated by animated charts which compare the results of a series of patients who received intravenous thiopental sodium (pentothal sodium®) with a group who received gas-oxygen-ether anesthesia. Various factors, such as stillbirths, neonatal mortality and type of delivery, were compared with the two methods of anesthetic management. The effect of the anesthesia on spontaneous and operative deliveries was also presented. Some obstetricians may not approve the large percentage of forceps deliveries illustrated. They do not tell us how many times it was necessary to use oxygen and how near some of the mothers came to serious collapse. The multiplicity of charts was confusing, and it is suggested that a clearer presentation could be made if fewer and only the most essential charts be used. Animation of the charts was excellent.

The sequence showing the preparation of thiopental solution could be satisfactorily deleted, particularly since these scenes are photographically poor in comparison with the excellent photography of the rest of the film. The conditions of preparation of thiopental should be criticized, particularly when the thiopental solution may be stored for three or four days. The possibility of contamination of the solution is ever present unless sterile gloves are worn during its preparation. The total dosage of thiopental was shown only once and then was combined in a chart presenting maternal and fetal blood levels at various minutes following the intravenous injection. It would be wise to indicate more definitely the dosage, so that a clearer impression of the dosage range could be obtained. Although the text stressed the use of mask oxygen during thiopental anesthesia, this practice was not sufficiently demonstrated. No mention was made of the advantages in the use of 50-50 mixtures of nitrous oxide–oxygen during thiopental anesthesia in decreasing the amount of thiopental and increasing the blood oxygen level.

Brief views of a multiplicity of surgical procedures were presented, including Rubin's test, vaginal delivery with low forceps, breech or spontaneous, and abdominal delivery by cesarean section. The insufficient relaxation obtained from thiopental sodium for version and extraction was discussed. The immediate postoperative care of the infant was wisely included. One wonders whether it is necessary to put a patient to sleep to do a sterile vaginal examination and rupture the membranes or if it is necessary in order to do a dilatation and curettage after an incomplete abortion; certainly it is not necessary to do so in order to apply the Rubin test. The technic after delivery shows potential contamination from holding the baby too close to the vulva.

This film portrays a new method of anesthesia in obstetrics; however, repeated viewings are necessary to grasp the message. A simpler script would present its message much more forcefully and with less confusion in the viewer's mind. It would be of interest to trained anesthesiologists but might be misleading to others in its present form.

**This Way to Nursing.** 16 mm., black and white, sound, 700 feet (1 reel), showing time twenty minutes. Prepared in 1948 at the Mt. Sinai Hospital, New York. Officially endorsed by the United States Public Health Service, National Student Nurse Recruitment Committee of the American Hospital Association and the National Committee on Careers in Nursing. Produced and procurable on rental or purchase from Emerson Yorke Studio, 36 West 45th Street, New York 19.

This film is designed to show the theoretical and practical instruction in a student nurses' course of an accredited school of nursing. It begins with the student nurse's entrance to school and depicts her six month trial period, at the end of which she receives her cap. The classrooms for teaching such subjects as chemistry, biology, anatomy and nursing arts are well illustrated. The student is portrayed at the bedside of the patient applying her knowledge of nursing arts and also is shown attending patients in the outpatient clinic. The sequence on bed making is rather long and overdone. The dignity of the profession is stressed and the production is appealing without forcing the point. The recreational facilities and social activities of the school are well demonstrated. The film terminates by showing various fields of nursing in which a graduate may serve. This motion picture will be of interest to groups who are concerned with nurse recruitment.

## NEW MEDICAL MOTION PICTURE ADDED TO A. M. A. MEDICAL MOTION PICTURE LIBRARY

**Polio Diagnosis and Management.** 16 mm., black and white, sound, 2,290 feet (1 reel), showing time fifty-seven minutes. Prepared in 1948 by H. J. Seddon, Professor of Orthopaedics, Oxford University, London, and others. Produced by Crown Film Unit, London. Procurable on loan (service charge $4) from: Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

The major portion of this film deals with a careful review of the diagnostic signs of early and more advanced poliomyelitis. By means of well prepared charts, it illustrates the incidence of poliomyelitis in Great Britain, where a decided increase occurred since the condition was first encountered in 1912.

The condition of 1 patient is followed from the time of the earliest symptoms until the last stage of a well planned program of rehabilitation, which includes the employment of physical medicine, psychosocial adjustment and vocational retraining in an attempt to achieve maximal function and adjustment of the individual and to prepare him physically, mentally, socially and vocationally for the fullest possible life compatible with his abilities and disabilities.

It is recommended especially for general practitioners, pediatricians, orthopedists, physiatrists and neurologists who desire a description of the diagnostic aspects of poliomyelitis as related to over-all management of the disease.

The rather unconventional use of the term "polio" in the title results from the fact that the idea is advanced that poliomyelitis and polioencephalitis can be considered as one disease.

This is a well planned educational motion picture. The photography is good.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Diagnostic Cutaneous Reactions to Intradermal Injection of Natural and Artificial Antibody and of Antigen Prepared from Streptococci Isolated in Studies of Diverse Diseases. E. C. Rosenow.—p. 485.

Trimeton in Treatment of Allergic Diseases. F. W. Wittich.—p. 497.

Environmental Excitants of Idioblastic Allergy (Inhalants). A. F. Coca.—p. 501.

Dust-Seal: Its Use in Avoidance of "House Dust" by Dust-Sensitive Persons. A. F. Coca.—p. 506.

Reactions to Histamine Iontophoresis in Therapy of Multiple Sclerosis: Preliminary Report. H. A. Abramson.—p. 511.

*Sensitivity to Mercurial Diuretics: Report of Case of Urticaria Due to Mercupurin. P. M. Gottlieb.—p. 518.

Comparative Study of Commercial Nebulizers. G. F. Harsh.—p. 534.

Allergic Rhinitis: Complete Dental X-Ray Examination in Search for Dental Foci of Infection. M. Millman.—p. 547.

Multiple Sclerosis—Treatment with Histamine and *d*-Tubocurarine. H. D. Jonez.—p. 550.

Chemical Concept of Immunity. W. J. Suer.—p. 564.

Clinical Observations with Thephorin—New Antihistaminic Drug. L. Sternberg and J. Gottesman.—p. 569.

Adequate Diets in Advanced Chronic Asthma. G. L. Waldbott, J. J. Shea and M. M. Harrington.—p. 572.

*Sensitization to Petrolatum in Ointment Bases. S. J. Levin and Selma S. Moss.—p. 579.

Study of Atopic Eczema: I. Further Observations on Allergy to Human Dander. II. Cutaneous Reactions to Eczema Scales. F. A. Simon.—p. 584.

Ragweed Dermatitis: Therapy by Oral Route. B. J. Slater and N. Francis.—p. 594.

**Sensitivity to Mercurial Diuretics.**—Gottlieb shows that mercurial diuretics may act as allergens, giving rise to a variety of clinical manifestations and even fatalities. These potent drugs may also produce untoward reactions by any one of several other mechanisms, of which may be mentioned primary toxicity of the mercury, especially on the heart, disturbances of plasma volume and fluid balance, electrolyte imbalance, "speed shock," overdigitalization and renal complications. Hence, it is incumbent on the physicians to study each such case as carefully as possible in an effort to determine the cause. From the allergic standpoint, patch-abrasion and patch tests would appear to be the most informative. Fortunately, the over-all incidence of untoward reactions to these valuable drugs appears to be low. A case is reported in which generalized urticaria followed the fifth and sixth injections of mercurophylline. The causation of the eruption was confirmed by a positive patch-abrasion (scratch-patch test). The minute amount of the drug absorbed from the test site evoked a focal reaction in the form of further urticaria. It is recommended that the scratch-patch test be more extensively employed in suspected drug allergy.

**Sensitization to Petrolatum in Ointment Bases.**—Levin and Moss direct attention to the fact that many of the patients with chronic dermatitis presenting themselves for allergic study have been under treatment for months or years. These patients have had many ointments prescribed, the bases of which almost invariably contain petrolatum. Sensitivity may be acquired more readily through the broken than through the normal skin. The conditions for the acquisition of secondary sensitivities in cases of dermatitis are ideal; i. e., the repeated and frequent application of a substance to the broken skin over a long period of time. It is not surprising, therefore, that under these conditions sensitivity to medicaments is frequently encountered. Six cases of definite sensitivity to petrolatum or related substances are reported. Patch tests on normal skin for purified petrolatum rarely elicit positive reactions. Usage tests are a valuable means of making a diagnosis of petrolatum sensitivity. The results may be positive on affected sites and later negative on the same healed sites. In view of the widespread use of ointment bases containing petrolatum and/or mineral oil for the local treatment of the allergic dermatoses, the possibility of sensitization to these items should be kept in mind. Recently the authors have encountered 4 additional cases of definite sensitivity to petrolatum. These patients were all negative to patch tests and positive to the usage tests carried out on the affected sites.

Further Experiences with Peritoneal Irrigation for Acute Renal Failure: Including Description of Modifications in Method. H. A. Frank, A. M. Seligman and J. Fine.—p. 561.

**Cytologic Method in Gastric Cancer.**—Ulfelder and his associates made a study of the most suitable technic for the cytologic study of the gastric contents in patients suspected of having cancer of the stomach. Particular emphasis has been placed on the method of collecting fluid. A number of additional openings are made in a size 14 Levine tube. It is introduced through the nostril; the patient is allowed to drink tap water to facilitate this maneuver. The stomach is then evacuated. This is the first specimen. One hundred cubic centimeters of isotonic sodium chloride solution is injected, the tube is clamped and the patient lies first on one side, then on the other, then on his face, and finally sits up or walks. The saline solution is partially withdrawn and reinjected several times during this procedure. Finally the stomach is again aspirated until empty. Both samples of fluid are centrifuged immediately, the supernatant fluid poured off, and thin smears made from the sediment. These are fixed and stained by Papanicolaou's method. Forty-eight patients have been studied in this fashion. Satisfactory cellular preparations were secured in 45 cases. Operation has disclosed carcinoma of the stomach in 14, and 12 of these were diagnosed correctly by this method. The accuracy of this method of diagnosis has increased since the introduction of the modifications described.

**Vagotomy in Idiopathic Ulcerative Colitis and Regional Enteritis.**—Dennis and his associates sectioned the vagus nerves in a girl, aged 20, who previously had undergone removal of the entire colon and five sixths of the ileum, and in whom severe involvement of the remaining bowel failed to respond to conservative measures. Vagotomy plus revision of ileostomy resulted in great improvement. This result prompted the authors to employ vagotomy in 4 patients without other surgical therapy. After six months 3 of these patients presented normal proctoscopic findings, and the fourth was reported as "healed ulcerative colitis." Of 28 patients who have been subjected to vagotomy since then, 25 were available for follow-up. Most of the clinical results have been encouraging in idiopathic ulcerative colitis as well as in regional enteritis. The response is usually best in cases in which there is not great loss of distensibility of the colonic wall. Patients with extensive fibrosis in the bowel wall, as a result of colitis, may take many months to improve after vagotomy. The mechanism by which vagal section changes the course of idiopathic ulcerative colitis is unsettled. The reduction in colonic tone which regularly follows vagotomy would suggest that relief of spasm is important. It appears possible that much of the benefit may accrue from protection of the mucosa from the reflex effects of the violent emotional stress to which these patients are subject.

**Polythene as Fibrous Tissue Stimulant.**—Yeager and Cowley point out that the irritating properties of cellophane have been utilized in obliteration of aneurysms and interruption of large vessels. Cellophane and cellophane-polythene (polyethylene) have been recommended because of physiologically inert characteristics and lack of fibrous tissue-stimulating characteristics. Clinical use is being made of a similar or related substance with end results that are diametrically opposed. Correspondence with the du Pont Company revealed that there is apparently some confusion in identity between cellophane and polythene. Polythene-du Pont is a long-chained polymer of ethylene. This product is polythene with less than 1 per cent of dicetyl phosphate. On the basis of animal experiments the authors believe that pure polythene does not cause a fibrous tissue reaction. Polythene film prepared by the "stripping process" of the du Pont Company is adulterated by dicetyl phosphate, which apparently is the tissue-excitant factor. The effects of polythene-du Pont on a diffuse dilatation of common carotid artery and on a fusiform aneurysm of the abdominal aorta are illustrative of the clinical application of the principle of treatment by fibrosis. After presenting the histories of these 2 patients the authors discuss implantation of polythene–du Pont into the abdominal wall, having used such implants in 11 inguinal and 4 ventral hernias. They conclude that the principle of tissue fibrosis offers a method of obliterating aneurysms and may be useful in fascial defects and recurring hernias. Conflicting results regarding the use of polythene in aneurysms, patent ductus arteriosus and obliterative procedure are probably due to variances in method of manufacturing the film. Implantation of polythene–du Pont when fibrous tissue reaction is not indicated would be most undesirable. Clinical use of cellophane, polythene or any other plastic requires knowledge of both the chemical and the physical characteristics of the product being used.

**Endothelioma of Bone (Ewing's Sarcoma).**—According to Coley and his associates there exists a specific type of malignant bone tumor, now designated as endothelioma or Ewing's sarcoma, which is a disease entity. Earlier pathologists classified this tumor with the heterogeneous and inclusive category "round cell sarcoma." The authors review the cases of Ewing's sarcoma observed at the bone tumor service of Memorial Hospital of New York during the thirty year period from 1918 through 1947. They take into consideration only the histologically proved cases, which number 91. Attention is called to the predominance of the male sex, the preponderance of cases in the age group from five to 25 years and the simulation of an infectious or inflammatory process as evidenced by frequent febrile reaction, leukocytosis and even the roentgenographic appearance. Sometimes it is difficult to distinguish this disease from osteogenic sarcoma. Securing microscopic confirmation prior to treatment is important because of the masking of the histologic picture following even small doses of roentgen therapy. In young children Ewing's sarcoma may be difficult to distinguish from metastatic neuroblastoma; in older children, adolescents and young adults, reticulum cell sarcoma of bone and angiosarcoma may closely resemble it. The more favorable prognosis of reticulum cell sarcoma of bone and its response to smaller doses of roentgen rays than are required to inactivate Ewing's sarcoma make its recognition important. Treatment of Ewing's sarcoma has yielded poor results. Only 3 out of 73 patients survived five years or more. Regardless of the method employed, the ultimate result is practically always death from widespread metastases.

Prognostic Significance of Incidental Acute Somatic Disorders in the Course of Psychoses: Reevaluation of Five Cases Fourteen Years Later. A. Gordon.—p. 646.

**Arteriovenous Aneurysms of Brain.** — Olivecrona and Riives say that among 3,206 verified brain tumors treated at their clinic, there were observed 60 cases (1.8 per cent) of arteriovenous aneurysms. The condition is about twice as frequent in men as in women. In 5 cases the blood supply came largely through branches of the external carotid artery. In 2 cases the aneurysm was located in the distribution of the vertebral artery. In the remaining cases the blood supply came exclusively from branches of the internal carotid artery. The cardinal symptoms of arteriovenous aneurysm are epilepsy, subarachnoid hemorrhage and intracerebral hemorrhage with hemiplegia. A systolic murmur was observed in only 8 cases. It is always present when branches of the external carotid artery contribute to the blood supply of the malformation. A typical calcification was observed in 6 cases. Epileptic fits were not only the commonest initial symptom but the most constant symptom of all. Headache was a frequent complaint but was not usually characteristic. A choked disk was observed in only 25 per cent of the cases. Mental changes were frequent. Encephalographic studies were carried out in most cases. The most frequent observation was cerebral atrophy. Sometimes the malformation was large enough to cause dislocation, suggestive of an expanding lesion. The diagnosis of an arteriovenous aneurysm should always be confirmed by arteriographic study, preferably by the percutaneous injection of iodopyracet. Both lateral and frontal exposures should be made. The authors agree with Cushing and Bailey that ligature of accessible arteries is useless. Decompression is rarely indicated, since pressure symptoms are habitually absent. Ligature of the carotid artery is inadvisable, because it involves the risk of hemiplegia and its effect on the lesion is uncertain. The choice lies between removing the lesion and leaving it alone. In the latter case roentgen treatment may be tried, even if not much is to be expected from such therapy. In the present series the aneurysm was removed in 24 cases, with 3 fatalities. One third of the total number of patients operated on are practically well.

**Headache a Symptom in Cervical Disk Lesions.**—The Raneys call attention to the fact that many patients complain of a headache when, in reality, the discomfort is in the neck. Many persons subject to soreness, stiffness, aching or pain in the lower cervical, pectoral or brachial region decide that these symptoms are due to neuritis, rheumatism, arthritis or a cold settled in the neck. Assuming the condition to be benign, the patient disregards it. If, however, the discomfort later extends to the head, he fears that the headache is a premonitory sign of serious illness; he complains to his physician of the headache and may never tell him of the associated symptoms. Lesion of the cervical disk is one of the commonest pathologic conditions of the cervical portion of the spine, and one of the commonest symptoms resulting therefrom is headache. Headache due to pathologic cervical disk is generally associated with such symptoms, so that the responsible factor is suspected when a detailed history is obtained, and the diagnosis is established by characteristic physical and roentgenographic findings. In adults, especially, lesions of the disk are sufficiently common so that not infrequently they are associated with other pathologic processes. One must be cautious in assuming that the proved pathologic disk is the only lesion present unless it suffices to explain all the symptoms and signs. Headaches following spinal puncture or head injury, for example, are aften due to lesions of a cervical disk. The authors present cases in which headache was due to a lesion of a cervical disk.

**Thrombopenic Purpura Complicating Gold Therapy.**—Mettier and his associates point out that during the past seven years in the wards and outpatient department of the University of California Hospital, 160 patients on whom a diagnosis of rheumatoid arthritis had been made were given gold salt therapy. During the treatment in 4 of the patients thrombopenia and purpuric manifestations developed. In 3 patients there was a spontaneous remission and the hemorrhagic tendency disappeared in about one week's time. In the fourth patient there was a second occurrence of thrombopenia which persisted for four months and finally failed to respond to transfusion. Splenectomy was followed by a dramatic rise in the blood platelets and recovery of the patient. In none of the other reported cases of thrombopenia secondary to gold therapy had splenectomy been attempted. In the present case the mild hemorrhagic disturbance of four months' duration became suddenly accelerated by the appearance of severe bleeding from the mucous membranes. It was felt that since the life of the patient was in danger splenectomy was advisable. Soon after the operation there was a dramtic response of the platelets which led to the recovery of the patient.

**Coagulation Time in Hemorrhagic Disease.**—Quick and his associates mention the different methods that have been recommended for the determination of the coagulation time and point out that this test is one of the most prone to be misinterpreted. On the basis of their critical evaluation of this test, they emphasize that the coagulation time is a measurement of the intrinsic power of the blood to convert fibrinogen to fibrin. It is an empiric test no matter how performed, and therefore in order to be reliable must be done on venous blood under strictly controlled conditions. A recommended procedure is outlined. The coagulation time is prolonged in hemophilia, hypoprothrombinemia, afibrinogenemia and heparinemia. In hemophilia, the coagulation time theoretically is a measure of the severity of the disease but practically is of limited value since the coagulation time may be within normal limits in some patients; the prothrombin consumed in the coagulation of hemophilic blood is therefore a better guide for diagnosis. The coagulation time in hypoprothrombinemia is relatively little prolonged until a drastic reduction occurs. The test is therefore of no value for establishing a hemorrhagic condition in hypoprothrombinemia. In afibrinogenemia the blood is incoagulable. A small amount of fibrinogen restores the coagulation time to normal. The presence of heparin increases the coagulation time. The test is therefore useful in controlling the therapeutic action of *this drug*.

**Hemorrhagic Diathesis with Anticoagulant in Blood.**—Soulier and Burstein of Paris say that the American literature records 3 observations of the presence of an anticoagulant in the blood of patients with hemorrhagic diathesis. They report studies on the blood of a fourth patient, in whom hemorrhagic diathesis was associated with the presence of an anticoagulant. The patient, a man aged 21, appeared to have hemophilia. The blood and plasma were strongly anticlotting and had a long clotting time. The clotting time of recalcified citrated plasma was greatly delayed by removing the platelets. Freezing and thawing of platelet-rich plasma resulted in a decided shortening of the clotting time. Dilution of the plasma shortened the clotting, while the addition of calcium and storage of the plasma had no effect. The prolonged clotting time was not corrected by the addition of normal plasma or plasma fractions having antihemophilic activity. The prothrombin time was nearly normal. Small quantities of thromboplastin were effective in shortening the clotting time. The anticoagulant had no antithrombin activity. The "progressive" antithrombin and antifibrinolysin of the patient's plasma were normal. The anticoagulant acts during the first phase of coagulation by inhibiting an (plasma) *activator of prothrombin*.

**Oral Use of Streptomycin and Succinylsulfathiazole in Ureterointestinal Transplant.**—According to MacLean and his associates, Morton has shown that the floral content of the bowel can be reduced by the oral administration of streptomycin to an exceedingly low level, and in many cases no growth was obtained after administration on culture of the stool. To achieve this, preparation of the bowel is commenced one week prior to operation by giving succinylsulfathiazole orally. In addition, streptomycin, 4 Gm. daily, is given orally (in orange juice), commencing three days prior to operation. The authors have used this technic in 3 cases of ureterointestinal transplants in which 4 operations were done. Cultures taken from the bowel when it was opened at operation showed no growth in 1 case and very light growth of the usual flora on three occasions in the remaining 2 cases. The author believes that by preoperative preparation of the bowel with succinylsulfathiazole and streptomycin orally, the bacteriologic flora can be reduced to a nonpathogenic level at the time of operation. Contamination of the peritoneal cavity, if it should occur, is then of negligible significance.

**Patent Ductus Arteriosus.**—Clagett reports the case of a girl, aged 19, whose infected patent ductus arteriosus was successfully operated on. The lesion was infected with Streptococcus viridans. Five days after admission to the hospital intensive penicillin therapy was begun. Approximately 1,000,000 units was given daily for six days by continuous intramuscular drip in the anterior thigh muscles. Total dosage was 5,340,000 units. The temperature became normal twenty-four hours after the penicillin was begun. Carinamide, 3 Gm. every three hours by mouth, was started two days after penicillin was begun in an attempt to produce higher penicillin levels in the serum. After taking 52 Gm. of carinamide, the patient vomited once, retained the next dose, vomited the next dose, and then took two final doses of 3 Gm. each. She then had received a total dosage of 64 Gm. in forty-eight hours. The drug was discontinued at this time because of a temperature rise to 104.4 F. It was felt that this was a drug reaction. At operation a patent ductus arteriosus was found, was ligated and divided. A flap of free pleura was sutured between the two ends of the divided ductus. Penicillin was continued postoperatively, 100,000 units every two hours (intramuscularly) for six days and then 30,000 units every three hours for two days. This patient has been followed over one year and has been asymptomatic and afebrile.

**Streptomycin in Granuloma Inguinale.**—Chen and his co-workers treated 100 patients, 65 men and 35 women, with laboratory proved granuloma inguinale, by intramuscular administration of streptomycin dissolved in distilled water containing 20 to 30 per cent of a 1 per cent solution of procaine hydrochloride. Sixty-seven of the patients had been treated before with some forms of antimonial preparations, but had not been benefited permanently or at all. The remaining 33 patients had not received any specific medication prior to admission. All the patients were arbitrarily divided into three groups regardless of their duration of disease and previous medication. Thirty-two patients were treated six to sixty-two days with a daily dose of 0.3 to 2.0 Gm. of streptomycin. Sixty-one patients were treated with a uniform dosage schedule of 4 Gm. per day for five days. The remaining 7 patients, who had extensive lesions, were treated with 4 Gm. per day for six to ten days. In all cases the antibiotic was administered in divided doses every four hours. Results showed that streptomycin so far constitutes the best treatment for granuloma inguinale. It is effective even in small dosage, though recurrences are more frequent and there is danger of creating streptomycin resistance, as in 2 of the authors' cases. The optimum daily dosage probably is 4 Gm. in divided doses. For average cases of granuloma inguinale a five day course is generally sufficient to effect a cure with disappearance of Donovan bodies and complete healing of the lesions with depigmented cicatrization in one to two weeks. For patients with extensive lesions or in whom clinical and microscopic responses are not so prompt, a ten day course is probably to be preferred.

**Streptomycin and Sulfadiazine in Influenzal Meningitis.**—Yampolsky and Jones treated a great number of patients, mostly children below 3 years of age, who had influenzal meningitis, due to Hemophilus in 95 per cent of the cases, with sulfadiazine and streptomycin alone, eliminating Alexander's rabbit serum. Sulfadiazine was given in a dose of 1½ grains per pound (0.22 Gm. per kilogram) of body weight per day for approximately seventeen days. If the patient could not take the drug by mouth it was given subcutaneously. One gram of streptomycin dissolved in 8 cc. of water was administered daily in eight divided doses of 1 cc. every three hours by intramuscular route for four to seven days, according to the seriousness of the illness. At the same time 30 mg. of the drug was given intrathecally for the same number of days. Except where spinal block was present and where streptomycin had to be given intrathecally, both by the lumbar route and through the cistern, the patients usually recovered and patients, no matter how young, got well without residual symptoms.

**Influenzal Meningitis.**—At the Cook County Hospital, during the period of 1942 to 1948 Levinson treated 60 children with influenzal meningitis. Six children given sulfonamide compounds alone died. Of 12 patients given sulfonamide compounds and serum 6 died. Of 9 patients given sulfonamide compounds, serum and penicillin only 1 died. One of 2 patients who were given sulfonamide compounds and penicillin died. Twelve patients received streptomycin, sulfonamide compounds, penicillin and serum, and 3 of them died. There was not a single fatal case in 17 patients who were treated with streptomycin and sulfadiazine. Two patients given streptomycin alone survived. Three hundred thousand units of streptomycin every six hours by intramuscular route for seven days proved of definite value in the treatment of influenzal meningitis and should replace all other types of treatment, but whether it can be used alone or should be combined with sulfonamide compounds time will tell. At present the author advises treating all patients with streptomycin combined with sulfadiazine in spite of the fact that 2 patients recovered on streptomycin alone. Sulfadiazine may be given intravenously beginning with an average of 3 grains of sodium sulfadiazine per pound (0.44 Gm. per kilogram) of body weight in twenty-four hours. It should be reduced gradually to 1 grain per pound (0.15 Gm. per kilogram) and as soon as possible should be given by mouth. Treatment with sulfadiazine should be continued for five days after the streptomycin is discontinued.

**Oral Penicillin in Pneumococcic Pneumonia.**—Volini and his co-workers treated 48 patients, 31 aged less than 50 and 17 aged over 50, who had the severe type of pneumonia, with penicillin by mouth. A primary dose of 200,000 units was given shortly after admission to the hospital, and one tablet containing 100,000 units was then administered every three hours day and night. The average total dose was 4,410,000 units, and the average duration of treatment was 5.8 days. Adequate therapeutic levels against pneumococci were demonstrated by penicillin assay of the blood. No attention was paid to the time relationship of penicillin administration to food intake. Specific buffering agents were not employed. There were 3 deaths in this series, 6.3 per cent in all and in the typed pneumococcic group 7.6 per cent. This is much less than the total death rate reported in patients with pneumonia who were treated with sulfathiazole, sulfadiazine and sulfamerazine. The major deterrent to oral penicillin therapy in the indicated dosage is the cost of this medication. The severity of the infection has been observed to have slight relation to the dosage of the drug required, providing therapeutic blood levels are maintained. The sensitivity of the pneumococcus to penicillin is marked and is the determining factor in dosage. Bacteremia responds to the dosages advised. Complications such as meningitis, empyema and acute bacterial endocarditis are refractory to almost any dosage and usually require local or topical administration. Atypical pneumonias should be given therapy like that for pneumonias of pneumococcic causation. The oral treatment of pneumonia by penicillin in the dosage and by the methods described proved as satisfactory as, if not superior to, treatment with sulfonamide compounds and almost the equal of parenteral penicillin treatment.

**Bone and Joint Changes in Hemophilia.**—Ghormley and Clegg say that in a series of 76 patients with hemophilia examined at the Mayo Clinic, 44 showed evidence of pathologic changes in the bones or joints. Weight-bearing joints were involved more frequently than non-weight-bearing joints, and the knee was involved about twice as often as any other joint. Ten of the 44 patients with hemarthrosis had single joints involved, while the other 34 had multiple joints involved. The authors report the histories of 6 patients with unusual bone lesions. In 4 the femur was involved, in 1 the thumb and in 1 the olecranon. These 6 cases seem to be examples of the so-called hemophilic pseudotumor. It was impossible to determine whether these hematomas were extensions of the hemorrhage from a neighboring joint or were subperiosteal or intramedullary in their origin. The case of the physician, which was followed over the longest period, seems to indicate that the hemorrhages were intramuscular and subperiosteal and caused destruction of the bone more by pressure erosion than by any other action. It is impossible to state whether or not there may be any "chemical effect," as postulated by Reinecke and Wohlwill. It would seem reasonable to conclude that these pseudotumors may arise, first, from hemorrhages originating in the joint, extending along the bone to produce pressure erosion; second, from subperiosteal hemorrhages, which first lead to formation of new bone and later to absorption and destruction of bone, and, third, from cortical or medullary hemorrhage, which may lead to cystic changes and later may destroy the bone or lead to fracture and further hemorrhage. It is important to be able to recognize the condition early enough so that the destructive changes may be kept under control.

**Cup Arthroplasty of Hip.**—Bickel and Babb say that a total of 274 hips in 233 patients were subjected to cup arthroplasty at the Mayo Clinic between 1939 and 1945, and a complete follow-up of this group has now been made. Patients who were advised to have cup arthroplasty were having sufficient pain so that they demanded operative intervention for its relief. Many patients who felt that they were having sufficient distress to warrant an operation were advised to pursue conservative treatment. This consisted in limited activity, reduction of weight, use of a cane or crutch, physical therapy and the taking of acetylsalicylic acid. Patients who had unilateral disease of the hip and whose occupations required heavy manual labor were advised to have arthrodesis of the hip. For cup arthroplasty the authors employed mainly the technic advocated by Smith-Petersen. When the acetabulum was too shallow for the cup, it was either reamed out or supplemented by a shelf to allow room for a freely movable cup. In cases in which ankylosis was nearly complete and a deep acetabulum was present, a portion of the head of the femur was left in the acetabulum to make it more shallow. The result was considered to be very good when the patient had no pain, could walk up and down stairs, tie his shoes and walk without assistance and without a noticeable limp. A good result was considered when the patient had little or no pain, could walk up and down stairs and could walk without assistance or with the help of a cane. Patients were considered to have a fair result when they were satisfied that improvement had been obtained and pain was less severe than before operation. The poor results were those in which the condition was not improved. Results were poor in slightly more than a fourth of the patients. The greatest percentage of good and very good results were obtained among patients of middle age, with a tapering off in the younger and older ages. The females did slightly better than the males, probably because the males use their hips for heavier work than do females. The authors say that those opposed to cup arthroplasty will focus their attention on the percentage of poor results. It must be remembered, however, that the patients were severely disabled before operation and that the percentage of salvaged persons far outweighs the percentage of those who have been made no better. Vitallium cup arthroplasty of the hip is a procedure which offers relief from pain, increased motion and correction of deformity to many patients.

**Penicillin Therapy in Acute Hematogenous Osteomyelitis.**—During the past four years Altemeier and Wadsworth studied 71 cases of acute hematogenous osteomyelitis in which treatment with penicillin was employed. Recognition of the disease must be on the basis of clinical signs and symptoms, without help from the roentgen ray, at the time when penicillin therapy can be expected to give excellent results in the majority of instances. In case of doubt, penicillin therapy should be started and continued until a diagnosis has been made. A dose of at least 20,000 units of penicillin should be given intramuscularly or intravenously, and repeated every two or three hours for at least seven days after the signs of infections are well under control. In severe infections, doses of 50,000 to 100,000 units may be given at the same interval until a clinical response has been obtained. A total dosage of at least 2,000,000 or 3,000,000 units, administered over a period of three or more weeks, seems adequate in most instances. Emergency surgical intervention is usually unnecessary, and conservative surgical procedures may be postponed until the infection has been controlled. However, large soft-tissue abscesses should be incised and drained early. During the acute phase of the infection, immobilization of the involved area is recommended for at least three weeks. Further immobilization is indicated in instances in which decalcification and rarefaction of the bone become considerable. Supportive therapy with blood transfusions, fluids, electrolytes and oxygen is indicated. Serial roentgenograms are recommended at intervals of one week during the early stages of the disease and at intervals of one month during later phases. The immediate results of penicillin therapy were striking. All but 1 of the 71 patients recovered; in the 1 exception, the patient was admitted to the hospital in a moribund condition. The return to function of the extremity was much more rapid than with previous forms of treatment. The results of penicillin therapy seemed to vary with the duration of the disease at the time the treatment was begun, with the dosage used and with the severity of the infection.

**Radioiodine in Exophthalmic Goiter.**—Haines and his co-workers treated 40 patients with exophthalmic goiter, 13 men and 27 women between the ages of 30 and 73 years, with radioiodine. Twenty-eight of the patients had recurrent exophthalmic goiter and from one to four attempts had been made to control the disease by surgical resection. Unilateral paralysis of the vocal cord was present in some of the patients. Seventeen patients had serious heart disease. Twenty-seven patients obtained good results, 8 fair results and 5 poor results from a single dose of $I^{131}$. Patients who obtained good results received an average dose of 242 microcuries per gram of thyroid tissue; those who obtained fair results, 239 microcuries per gram, and those who had poor results, 151 microcuries per gram. It would seem that an average dose of more than 200 microcuries per gram of thyroid tissue should be tried in cases in which an attempt is made to control the disease with a single dose. It is apparent that some patients treated this way will need a second dose of $I^{131}$ to control the disease. Some patients have needed much less than 200 microcuries per gram of thyroid tissue and doses considerably larger have failed to bring the disease of others under control. This suggests that there may be great individual variability in the sensitivity of different thyroid glands to radiation. The incidence of both myxedema and of recurrence of exophthalmic goiter after treatment was much higher in this series of patients treated with $I^{131}$ than among patients treated surgically. Much more experience is needed before one can have confidence in the accuracy of estimated doses. Thus far no serious reactions were noted by any of the patients treated with $I^{131}$.

**Effect of Estrogen on Lactation.**—Gershenfeld and Perlmutter report 501 women who were delivered at the Newark Beth Israel Hospital and who did not nurse. In 238 of these women, lactation was suppressed by administering 1.5 mg. of ethinyl estradiol daily in three equally divided amounts; this regimen was started on the day following delivery and was continued for the duration of the hospital stay, which varied from six to nine days. One hundred and twenty-eight nonnursing mothers formed a control series. In them the subsequent pain and engorgement of the mammary glands were treated by the administration of 200 mg. of camphor monobromate capsules four times daily, limitation of fluids, saline purgation and tight breast binding. During the hospital stay of the puerperal women pain and engorgement in the breast were most effectively relieved in those who received ethinyl estradiol, whereas the camphor regimen with other supportive therapy was highly ineffectual during the same period. There was no increase in the amount of blood in the lochia while under this estrogen medication and the number of instances of recognizable withdrawal bleeding was so small as to be negligible. On release from the hospital the women who were given ethinyl estradiol showed the highest percentage of continued difficulty at home with free leakage of milk, breast engorgement and pain, as compared with that of the group treated with camphor medication and supportive therapy, and even with that of the group of 101 nonnursing mothers who did not receive any treatment during their hospital stay. Difficulties experienced by the nonnursing mothers after omission of ethinyl estradiol could be reduced to a minimum if this medication were available to them after leaving the hospital. When it was not available, the regimen of camphor with supportive treatment appeared to be more successful in this respect only.

**Cholera Immunization.**—Singer and his associates compared the effectiveness of cholera vaccines which were prepared by different methods and tested the efficacy of different routes of administration. One strain of Vibrio cholerae which was isolated in Nanking during the epidemic of 1946 was used for the preparation of the vaccines. The strain was passed through 2 mice before being used for the preparation of vaccine. It was then grown on beef extract agar, the growth was washed in isotonic solution of sodium chloride and the suspension was passed through sterile filter paper. After that it was treated in one of various ways. Experiments were performed on different groups of men. From the result of this study the deduction may be drawn that heating to 56 C. and treatment with formaldehyde or alcohol produce vaccines of approximately equal potency as judged by the agglutinin-response of human subjects. Heating the vaccine to 100 C. seemed to increase its antigenicity, resulting in a better antibody response of the immunized men. Intracutaneous vaccination appeared to be more effective than subcutaneous injections; it was, however, in some instances followed by abscess formation, which, although insignificant in extent and not accompanied by discomfort, should be considered as contraindicating its general application.

**Diagnosis of Poliomyelitis.**—Abt distinguishes three broad clinical types of acute anterior poliomyelitis; namely, abortive, nonparalytic and paralytic poliomyelitis. Neither a clinical nor a laboratory diagnosis can be made for the abortive type of poliomyelitis, because in this systemic phase of the disease a single symptom or combination of any symptoms may be the forerunner of any acute infection. There is no involvement of the central nervous system at this stage of the disease, and therefore lumbar puncture will reveal a normal spinal fluid. Nonparalytic poliomyelitis may be diagnosed from history, symptoms and clinical signs and spinal fluid changes even though no paresis or paralysis develops, particularly in those cases which occur during a season of the year in which poliomyelitis is known to be prevalent and during epidemic periods. Such cases were common in Illinois during the summer and fall of the 1947 season. This second stage of the disease involves the central nervous system, and in addition to the general symptoms of fever, headache, anorexia, nausea and vomiting there may be stiffness of the neck and of the back. The most indicative signs for diagnosis are the spine sign (ventral flexion) and the head drop. If both these signs are absent, a positive diagnosis will probably not be made. If one or both are present with characteristic spinal fluid changes, a positive diagnosis should be relatively easy. If paralysis occurs, it usually develops on the second or third day of this phase of the disease. Pain, diminution or loss of the deep reflexes and weakness or twitching of muscle groups may be premonitory signs of approaching paralysis. Only a rapid method for virus identification could positively indicate whether many of the cases seen in Illinois this fall were actually due to the poliomyelitis virus or to such other known viruses such as that of St. Louis encephalitis, equine encephalomyelitis, a different strain of poliomyelitis, or a new and unknown virus. Until a rapid method for virus culture is obtained, only a presumptive and not a positive diagnosis of such cases may be made.

**Thermal Antibody Treatment of Poliomyelitis.**—Rappaport treated 20 consecutive cases of acute poliomyelitis in 14 boys and 6 girls between the ages of 2½ and 16 years with thermal poliomyelitis antibody. It was given intramuscularly into the lateral aspect of the thigh. Eight patients received 15 cc. each, 2 received 22 cc. each, one received 25 cc., 8 received 30 cc. and 1 received 40 cc., the dose varying with the severity of the illness and somewhat with the size of the patient. Only 1 patient had a very painful local reaction accompanied by a generalized reaction with temperature up to 104 F.; 17 patients had only a local reaction of pain and 2 patients had no reaction or pain. Improvements were noted as follows: The 5 patients who had difficulty in swallowing could swallow normally again within twenty-four hours to five days after receiving the thermal antibody, and the 3 patients with respiratory difficulties could use their intercostal muscles much better within twenty-four hours to five days after the treatment. The pain in the extremities of 4 patients disappeared on the third to the sixth day after receiving the antibody. None of the patients treated with the thermal poliomyelitis antibody died and in only 1 patient did more paralysis develop after this treatment. The 19 surviving patients were free from pain sooner than the untreated and moved about actively in a short period of time. The solutions of antibody used in treatment were prepared by autoclaving suspensions in isotonic sodium chloride solution containing streptococcus isolated from cases of poliomyelitis for ninety-six hours without hydrogen peroxide, or for one to three hours after adding 1.5 per cent of hydrogen peroxide. In both types of preparation it was observed that the bacteria disintegrate, the toxic components are destroyed and substances resembling antibodies become demonstrable in the supernatant sodium chloride solution. This antibody would seem to have curative effects in poliomyelitis and in returning the patient to normal activity in a relatively short space of time.

**Dissociation Between Pain and Temperature in Spinal Cord Lesions.**—Sherman and Arieff point out that in most textbooks of neurology and neuroanatomy it is generally stated that the fibers of the lateral spinothalamic tract convey the sensations of pain and temperature, leaving the impression that both modalities are conveyed in the same tract and that they suffer simultaneously in disease. The diagnosis of hysteria at times had been erroneously attached to a patient who suffers only the loss of pain sensation with preservation of temperature sense and vice versa. These misunderstandings exist in spite of the fact that there are definite contributions in the literature to indicate that these modalities may be lost differentially by lesions in the spinal cord. The authors present 4 cases which represent instances of dissociation of pain and temperature sense in intramedullary and extramedullary spinal cord disease. In the first case, temperature sense was present but diminished in areas of analgesia in two separated dermatome areas as a result of syringomyelia. In the second case, there was loss of temperature sense in an area where pain sense was well preserved in an intramedullary lesion. Because of this one may postulate separate pathways for pain and temperature. The third case showed preservation of temperature with loss of pain in the presence of extramedullary compression. The fourth case shows loss of pain and cold perception with preservation of warmth perception as a result of an intramedullary lesion. The authors conclude that the functional anatomy of the spinothalamic tract is still not completely understood.

*Preliminary Pharmacologic Investigation of the Tannin Obtained from Pinus Caribaea, Morelet. F. W. Bope, Elizabeth M. Cranston and O. Gisvold.—p. 209.

**Tannin from Slash Pine.**—Because of the success of tannic acid method of treatment of burns, Bope and his co-workers decided to investigate a substance which might eliminate or at least decrease some of the objectionable properties of tannic acid, but at the same time maintain or even increase its favorable properties. The pharmacologic investigation of the tannin obtained from Pinus caribaea, Morelet, was suggested after a consideration of the properties of this natural tannin and its ability to react with proteins in a manner similar to tannic acid. This experimental work gives a comparison of the relative toxicities of the phlobatannin of Pinus caribaea and tannic acid and a comparison of the effects of these two tanning agents in the local treatment of burns. The phlobatannin used in this work was crude phlobatannin obtained by defatting the inner bark of the slash pine tree Pinus caribaea, Morelet, extracting with 95 per cent alcohol, and then removing the alcohol by vacuum distillation. Tannic acid, injected intraperitoneally into mice, caused necrosis of the liver, whereas phlobatannin produced a different type of liver injury, namely, diffuse hepatitis. Phlobatannin has approximately one sixth of the acute toxicity of tannic acid. In the local treatment of burns, solutions of phlobatannin and of tannic acid were about equal in respect to time required for the formation of a complete eschar over the burned area. However, the eschars formed with phlobatannin remained completely intact slightly longer, were less stiff and brittle and were lighter in color than those produced by tannic acid. This experimental work indicates that Pinus caribaea phlobatannin possesses the beneficial properties of tannic acid in the local therapy of burns, but is decidedly less toxic.

Tuberculosis Case-Finding in College. R. I. Canuteson.—p. 416.

**Management of Eclampsia.**—Brown is of the opinion that eclampsia is the final clinical manifestation of a toxemic pregnancy. Its appearance suggests inattention on the part of the patient or her physician to obvious "storm warnings." Deaths from eclampsia seldom occur in patients receiving good prenatal care. The relegation of prenatal checkups to a nurse must be condemned. The regular recording of weight and blood pressure measurements and the critical interpretation of changes in these values are essential to the early detection of toxemia and the prevention of eclampsia. Any patient who gains more than 1 pound (453.6 Gm.) a week or 5 pounds (2,268 Gm.) a month, or whose diastolic blood pressure increases by more than 20 mm. of mercury, should be viewed with suspicion. The use of diets high in protein and low in salt largely eliminates the development of toxemia and eclampsia. Once eclampsia has supervened, individualization is essential. Deep sedation is necessary to control convulsions. Morphine, tribromoethanol and paraldehyde are suitable, the latter two avoiding an antidiuretic effect. Both extremes of dehydration and drowning are to be avoided. Fluid balance should be maintained by the infusion of 50 to 75 cc. of isotonic dextrose solution per hour. The interval induction of labor by the rupture of membranes will usually permit favorable termination of the pregnancy.

**Rectal Shelf and Pararectal Masses.**—According to Cooper, there is confusion concerning whether any mass felt anterior to the rectum and in the rectouterine or rectovesical space shall be called a rectal shelf or whether this term should be reserved only for cases in which there is a palpable ridge or ledgelike mass impinging against and attached to the anterior wall of the rectum and 4 to 10 cm. above the anus. Properly, the term "rectal shelf" has been employed to designate that condition in which a palpable mass impinging on or attached to the anterior rectal wall causes a ledge or shelf to be felt. Such a mass deserves serious evaluation because it may call attention to a lesion remote from the rectum. The mass may be confused with a primary carcinoma of the rectum and thus lead to an error in diagnosis and prognosis. A patient may consult a physician because of symptoms produced by the rectal shelf or a pararectal mass without relating any which result from the primary lesion, or the reverse situation may be encountered. The author reviews the literature with reference to rectal shelf and pararectal masses and presents a case report. The most common causes of pararectal masses among women are lesions of the genital system, and among men lesions of the gastrointestinal tract. When a rectal shelf or a pararectal mass is found a diligent search for the primary cause is imperative. A digital examination of the rectum and proctoscopic examination should be routine in cases of obscure malignant and inflammatory disease within the abdomen. Any suspected case of gastric carcinoma should have a digital examination of the rectum made in search of a rectal shelf or a pararectal mass. Hasty treatment or prognostic theories should not be entered into until a patient with a rectal shelf or a pararectal mass has been thoroughly studied. Not all pararectal masses or rectal shelves are caused by a malignant metastatic growth.

**Treatment of Syphilis in Pregnancy.**—A review of the literature on the treatment of syphilis during pregnancy convinced Horne and Curtis that penicillin is superior to all other antisyphilitic drugs in the prevention of prenatal syphilis. With penicillin the results are equally good no matter what the duration of pregnancy at the time of treatment. A total dose of 3,600,000 units of soluble penicillin is recommended. This can be given as 40,000 units every three hours for ninety doses. Preliminary studies indicate that penicillin in peanut-oil-beeswax may be an adequate substitute for aqueous penicillin. If this preparation is used, it is suggested that the mother receive 600,000 units daily for ten days. Adequate serologic and clinical follow-up of the mother and child is imperative. Routine retreatment during ensuing pregnancies of the mothers previously treated with adequate amounts of penicillin is not recommended if the maternal serologic reaction becomes negative and remains negative. There is no evidence that abortions are induced by treatment with penicillin during pregnancy. Massive arsenotherapy is the treatment of choice in patients who do not tolerate penicillin.

**Penicillin and Malaria in Neurosyphilis.**—This report by Curtis and Horne concerns 223 patients treated for some type of neurosyphilis who have been observed for a minimum of one year subsequent to treatment. Of these 108 received only penicillin and 115 were given therapeutic malaria plus penicillin. Patients with asymptomatic neurosyphilis, meningovascular syphilis and tabes dorsalis responded as well to penicillin alone as they did to combined therapy. This is seen in both the clinical and spinal fluid picture. The two groups with paresis and taboparesis responded as well clinically to penicillin as to malaria and penicillin, but the latter method retains a slight superiority in producing improvement in the spinal fluid findings after two years of observation. The authors believe that a longer period of post-treatment observation is necessary before a final conclusion can be drawn regarding this group. The response to the combination of malaria and penicillin therapy seems to be more rapid, but all things considered, the long term result from penicillin therapy alone may be just as good. It certainly is less hazardous.

**Smallpox.**—Zinneman reviews observations on 10 soldiers who contracted smallpox during the initial occupation of Southern Korea. All of them had been vaccinated at least once since induction into the Army, but made the statement that the vaccinations resulted in little more than one would expect of an ordinary scratch in the skin. Only 2 of the patients were vaccinated during civilian life. One of them had a scar from a vaccination nine years previously. His was the lightest case on record, the only one whose life never seemed to be in danger in spite of the fact that his skin lesions were confluent. The second one had no vaccination scar and believed he had no "take" when he was vaccinated at high school age. Both of these men recovered. The period from the probable exposure to the onset of symptoms was in all cases within the described incubation time of from eight to fourteen days. Exposure was provided by contact with Korean natives. The 10 cases under discussion were of the most severe variety. The initial symptoms were high grade fever, persistent vomiting and severe pain in the upper part of the abdomen. Headache was next in frequency, and only 2 patients complained of backache, although the literature describes backaches as a frequent initial symptom. Six of the 10 cases were classified as purpura variolosa, the severest form of smallpox. All the patients died. The sooner purpuric symptoms became evident, the more severe the toxicity of the disease and the shorter the duration to the fatal end.

**Disseminated Lupus Erythematosus Among Nurses.**—A follow-up survey on 750 nurses who were trained at a large municipal hospital between 1932 and 1946 revealed to Ayvazian and Badger that 3 of 13 fatalities in this group resulted after disseminated lupus erythematosus, this disease being second only to tuberculosis (4 cases) as the major cause of death. The histories of the 3 patients with lupus erythematosus are presented. A search was made for the factor common to these 3 cases. In 1 the apparent onset of the process coincided with Dick toxin reactions. The rash that appeared on her arm at the site of the inoculation persisted for a year up to the time of death, gradually transforming into the lesions of lupus. In case 2 no such definite correlation could be demonstrated. If, however, the change in the blood Hinton reaction can be accepted as an early serologic alteration of disseminated lupus, it is noteworthy that this occurred shortly after a series of inoculations had been completed. In case 3 the typhoid vaccination might be considered an associated allergen. It was after exposure to sunlight less than three months later, however, that the cutaneous manifestations of lupus first appeared. Fourteen months after the injections the patient died of lupus, having progressed rapidly through the final stages of the disease. Thus there is a possibility that an allergen was present in each of these cases.

**Arterial Grafts in Cardiovascular Defects.**—In the laboratory for surgical research Gross and his associates removed sections of abdominal aorta from donor dogs and subsequently used them to replace sections of the abdominal aorta of recipient dogs. Sixty-three such grafts were made in three sets: Vessels were removed from donor animals and implanted within a few hours into recipient dogs; segments of aorta were frozen and kept for varying periods before being implanted, and arterial segments were preserved for varying periods by storage in special nutritive solutions just above freezing before being placed in recipient animals. On the basis of observations in these animal experiments, it was believed that a method of arterial preservations might be applicable for vessel grafting in human subjects. Segments of arteries obtained within a few hours from human beings who died in automobile accidents were collected under aseptic conditions and stored for use whenever the need for an arterial graft might arise in a patient. Nine such grafts were used to bridge gaps between the aortic system and the pulmonary artery when it was desired to establish an aorta-pulmonary artery shunt for alleviation of the cyanotic state of tetralogy of Fallot, and when it was impossible directly to anastomose vessels of the aortic and the pulmonary systems by the Blalock or the Potts technic. One of these patients died twelve days after operation, largely from the effects of dicumarol[5] therapy. A second died two days after operation from cardiac decompensation. The grafts in both cases were patent. In the 7 surviving patients the grafts were apparently carrying blood and have been in place from one to five months.

**Chronic Megakaryocytic Myelosis.**—Ricker directs attention to the fact that the syndrome of chronic splenomegaly, weakness, leukemoid peripheral blood picture and myelofibrosis with osteosclerosis is described under a variety of terms. These include chronic nonleukemic myelosis, myeloid megakaryocytic hepatosplenomegaly, megakaryocytic nonleukemic myelosis and agnogenic myeloid metaplasia of the spleen. Ricker's is the seventy-seventh case to be reported. It concerned a man, aged 57. He was dyspneic and moderately cyanotic. Wheezy expiratory rales were heard. Examination of the abdomen revealed it to be distended by the spleen and by the liver. The patient failed suddenly, went into peripheral vascular collapse and died before blood studies could be performed. At necropsy the liver was enormously enlarged; the spleen likewise was enormous. Microscopically, the liver showed some necrosis. Sinusoids contained giant cells of megakaryocytic characteristics. Basic splenic architecture was unaltered, but extrafollicular parenchyma showed myeloid metaplasia, and there were numerous megakaryocytes scattered through this tissue. The reticulum of the lymphatic sinusoids also contained large numbers of megakaryocytes. The bones revealed osteosclerosis. The lesions were at first interpreted as Hodgkin's disease, but then the basic tissue was found to be myeloid in character and the giant cells proved to be megakaryocytes. The megakaryocyte is regarded as the sine qua non of this chronic myelosis. Confusion of the two forms of giant cells, megakaryocytes and Reed-Sternberg cells, as was done initially in this case, is understandable. Irradiation of the spleen and splenectomy have both been tried in numerous cases of this megakaryocytic myelosis, but they have no lasting effect and are contraindicated. The author is of the opinion that the process is probably malignant, an indolent myelogenous leukemia. The sudden death in this patient is unusual, because, whereas the final outcome of megakaryocytic myelosis is invariably fatal, it usually progresses slowly, survivals up to twenty years having been reported.

**Blood Volume Depletion in Surgical Cases.**—According to Scudder and his associates the chronically ill patient with loss of weight and debilitation has been recognized as a poor surgical risk. He is more susceptible to surgical shock, less able to tolerate a minimum of hemorrhage and more prone to have certain postoperative complications. He is notoriously intolerant of isotonic sodium chloride solution and frequently displays fluid and salt retention after such infusions. The term "chronic shock" has been suggested for this condition, and correlation has been shown to exist between increased susceptibility to shock and reduced circulating blood volume. The authors show that many clinicians are reluctant to accept the fact that only with the knowledge of the blood plasma volumes can the various blood constituents be described in their absolute values. This is reflected in the fact that few hospital laboratories are equipped for volume determination. The authors attempt to show that empiric judgment alone cannot be depended on in evaluating the level of a patient's circulating blood and plasma volume and that exact studies must be done as a guide to quantitative replacement of blood volume deficits. Much of the controversy as to whether the chronically ill, debilitated patients have a lowered blood volume stems from the difficulties involved in calculating a standard value in a patient in whom progressive loss of weight is involved. Such weight depletion is not associated with an actual reduction of the potential vascular bed. For this reason it has been found that blood volume deficits in depleted patients should be calculated on the basis of a standard for the usual weight prior to the illness. The concept of protein and hemoglobin masses in contradistinction to concentrations is stressed. The low protein and hemoglobin mass explains this type of patient's inability to tolerate surgery, especially his inability to lose even relatively small amounts of blood without suffering shock. Because the results of quantitative blood replacement have been so consistently satisfactory, the authors urge that the blood volume deficit be determined in all chronically ill patients for whom surgical treatment is contemplated.

**Fruit-Eating Bats and Rabies.**—Pawan says that as with blood-sucking vampire bats, so the saliva of fruit-eating Artibeus bats, though they may not manifest any evidence of rabies, may carry infection. Fruit-eating bats, when infected with rabies, may bite mammals, not necessarily with the object of obtaining blood for food, but on account of a change in habit through being rabid. In mammals so bitten rabies may develop. During the height of the 1929-1931 epidemic of rabies in man and animals in Trinidad, authentic accounts were given of bats flying from fruit trees and attacking animals and even man. The probability is that such bats were fruit eaters. While the destruction of the blood-feeding vampire remains the main objective in antirabies bat campaign, it should not be forgotten that fruit-eating bats, when rabid, may bite mammals, and measures for reducing their numbers should not be lessened. The average length of life of the Artibeus after artificial infection with rabies is 130 days.

Erythema Exudativum Multiforme in Childhood. A. V. Neale.—p. 183.

**Heart Block in Children Possibly Attributable to Measles.**—According to Clark heart block is an uncommon condition in childhood. The 3 cases reported here are of interest, since in all 3 there is evidence that complete heart block developed either during or shortly after an attack of measles. One patient had frequent Stokes-Adams attacks and died two years after the onset of the heart block. The other 2 patients, brother and sister, have had no symptoms directly referable to the heart block and are alive and well nine months after the block developed. It is suggested that in all 3 cases the heart block is the result of measles, but the possibility that rheumatic carditis and some familial weakness of the conducting tissues may have played a part in the causation in 2 of the patients is admitted.

**Penicillin in Neurosyphilis.**—Martin reports 24 cases of neurosyphilis in which penicillin treatment was used. Observations on these cases convinced him that penicillin is sufficient in most cases of neurosyphilis. Whether it is adequate or not for the cases of more acute dementia paralytica this series does not show. If, with the possible exception of such cases, the patient can be kept under observation after treatment and penicillin repeated if necessary, malaria will seldom be called for, and the risk of it will seldom be justified. Even if penicillin does not render malaria unnecessary, it is a potent weapon and will make us much less dependent on malaria. The author considers his conclusions as tentative because longer observation is necessary.

Epilepsy and Tetany. J. E. G. Pearson.—p. 680.

**Colic of Large Intestine Due to Sympathetic Deprivation.**—In each of the 2 cases reported by Ogilvie the symptoms so strongly suggested obstruction of the distal colon by a carcinoma that laparotomy was undertaken in spite of normal findings after a barium enema. In each case the operation disclosed a normal colon and extensive and entirely unsuspected malignant disease involving the region of the crura of the diaphragm and the celiac axis and semilunar ganglions. Since the author was unable to find previous reports of this condition he designates it as a new clinical syndrome. He believes that the symptoms and signs of colonic obstruction in these 2 cases occurring in the absence of organic disease of the colon itself can be explained in three ways: (1) that the tumor stimulated the parasympathetic supply to the colon; (2) that the tumor cells produced some substances stimulating peristalis, or (3) that the subdiaphragmatic growth had interrupted the sympathetic supply to the large intestine, so that the parasympathetic innervation, which in the distal colon comes from the second and third sacral nerves, was allowed to act unopposed. Of these three explanations the third alone is probable. In the 2 cases under discussion the malignant infiltration surrounded, and may well have put out of action or even destroyed, the splanchnic nerves, the semilunar ganglions and the celiac plexus. The vagi passed through the same invaded area and were equally liable to interruption—a fact that fits in with the observation that only that part of the bowel supplied by the caudal parasympathetic system gave clinical evidence of overaction. It may be objected that surgical interruption of the sympathetic nerves at the same site does not produce this effect and that it does abolish pain. The author replies to this objection that the interruption of nerve fibers by malignant infiltration may be selective, picking out the motor fibers before the sensory ones; that the sensory and motor fibers may not run together in all persons as they do in the majority, and that painful sensations, blocked in their normal pathways, may find others.

**Effect of H 11 on Malignant Disease.**—The substance H 11 is an extract prepared from a concentrate of normal male urine. Reports have appeared indicating that the substance has an inhibitory action on malignant tissues in the human being, and may in certain cases lead to recovery from cancer. Advocates of the alleged remedy have said that responsible bodies, in particular the Medical Research Council, were withholding support and refusing to recognize work which marks an advance in the treatment of cancer. It was therefore decided that the Medical Research Council should appoint a special committee to collect the available evidence on which the claims for H 11 were based and to assess its value. The conclusions at which the committee has arrived after careful consideration are: 1. It has not been possible to deduce from an anlysis of the records that H 11 has any effect either on the rate of growth of cancer in man or on the clinical course of the disease. 2. So far as the experiments in mice carried out under its direction are concerned no inhibitory action by H 11 has been demonstrated.

*Medical Examination of 500 African Railway Workers. H. C. Trowell—p. 311.
Pathology of Central African Natives. Mulago Hospital Post Mortem Studies—VIII. J. N. P. Davies.—p. 322.

**Cancer Among Europeans in Kenya.**—The annual cancer morbidity of the European population of Kenya is approximately 1 per thousand. The proportion of carcinomas to sarcomas was 9.6 to 1. The most frequent sites of carcinoma are breast, skin, genital organs and alimentary canal, in order of frequency. Sarcoma takes the form of bone tumors in a third of all sarcomas.

**Examination of African Railway Workers.**—The 500 railway workers examined by Trowell were Africans. Nearly all employees looked thin, but it is rare to see a stout African. Little food is usually taken before leaving home in the morning. Protein deficiency is unlikely to occur among persons who, like the railway workers, eat cereals and from 1 to 2 pounds (454 to 907 Gm.) of meat weekly. However, those who, like many tribes in Uganda, rely on tubers and fruits such as plantains, potatoes, yams and cassava to satisfy hunger must consume a diet low in protein. Some of the results obtained in the clinical examination of the Uganda trainees of the Transportation School may reflect protein deficiency. Discussing vitamin deficiencies, the author gives particular attention to what are usually regarded as manifestations of vitamin A deficiency. Xerophthalmia and follicular keratosis were fairly frequent. Little evidence of riboflavin deficiency was seen, and clinical signs of pellagra, which would indicate nicotinic acid deficiency, were rare. No case of scurvy was found. Caries of the teeth is rare. Disorders due to vitamin D deficiency are absent. Fifteen, or 3 per cent, of the 500 employees were absent owing to alleged sickness, but it is impossible to give a true estimate of the amount of sickness and the precise causes of sickness. In the dispensary of a locomotive shed, minor respiratory infections predominated, and malaria and tropical diseases appeared to be of little importance. The epidemicity of malaria in Nairobi is such that railway employees seldom contract an attack except during epidemics. Nairobi is in the Kenya highlands. It is difficult to know how far the heavy incidence of helminths and intestinal protozoa is responsible for ill health.

**Histopathologic Aspects of Dementia Paralytica After Penicillin.**—Smith and de Morais report 4 patients with dementia paralytica who died some weeks after parenteral penicillin treatment with total doses between 2,400,000 and 4,800,000 units. Two of the patients had improved clinically as well as serologically. Histologic examination of the brain in these 2 cases revealed inflammatory changes which were distinctly less intense than in untreated patients with dementia paralytica. The iron reaction was positive in all cases, but least intense in the 2 patients who had improved. The exacerbation of mental symptoms seen on the eighth day of treatment in 1 of these 2 patients was presumably a Herxheimer reaction. No spirochetes were found in any of the 4 brains. These findings closely resemble those found after treatment with malaria. The 2 cases in which there was no improvement were of the juvenile type. One of these patients, a woman aged 27, died thirty days from the start of treatment, after rapidly deteriorating both mentally and physically. The second patient, a youth of 20, showed no improvement during and after treatment with penicillin. He gradually deteriorated, both mentally and physically, and died sixty-six days from the start of treatment. The histologic studies in these 2 unimproved patients showed no mitigation of the inflammatory reaction. The 2 cases in which there was improvement suggest that treatment by penicillin alone is capable of influencing the pathologic progress of dementia paralytica.

**Dietary Protein and Liver Cytoplasm.**—Campbell and Kosterlitz describe a new method for the assay of the nutritive value of proteins in adult rats. It is based on the fact that the amount of labile cytoplasm present in the liver depends on the quantity and quality of dietary protein. Labile liver cytoplasm can be estimated by a determination of protein, phospholipin and nucleic acid or of the nonglycogen nonlipid liver solids. The quantity of nonglycogen nonlipid liver solids varies directly with the logarithm of the protein intake. The method can therefore be used at all levels of protein intake above minimum requirement. Regression equations are given for casein with normal and reduced caloric intake and for egg albumin. A reduction in caloric intake lowered the amount of nonglycogen nonlipid liver solids without altering the regression coefficient. Decreases of 20 and 47 per cent in caloric intake reduced the nutritive value of casein from 1 to 0.58 and 0.26 respectively. The effect of reducing caloric intake on the nutritive value of a protein is of considerable interest. Unless sufficient calories are supplied in the diet, part of the protein will be utilized for energy requirements. Nevertheless, labile nonglycogen nonlipid liver solids are still present in calory deficiency, although with decreasing food intake more and more protein nitrogen is required to obtain the same effect. That the regression coefficient is not significantly affected by the reduction in calories means that the response of the liver to increasing protein intake is only quantitatively but not qualitatively altered. Nutritive values of various proteins have been determined and found to be in fairly good agreement with those obtained by the older methods.

**Oral Administration of Streptomycin in Gastroenteritis.**—James and Kramer gave streptomycin by mouth to 30 children with gastroenteritis, in whose stools Proteus vulgaris was present. Four of these patients were selected for streptomycin therapy in the course of an outbreak of epidemic diarrhea among the newborn in a maternity hospital. Another group of 4 were selected among 12 children under 2 years of age, when an epidemic of gastroenteritis broke out in a residential nursery. The third group included cases of gastroenteritis in a children's unit including patients critically ill on admission and those not responding to routine treatment. The total dose of streptomycin was usually 2 Gm. administered over a period of seven days, 0.5 Gm. being given in the first twenty-four hours and 0.25 Gm. on each of the six subsequent days. The fraction of the daily dose that was given before each feeding was contained in 1 cc. Given in this way streptomycin was palatable and well tolerated, even where there had been copious vomiting. Streptomycin by mouth effectively eliminated Proteus vulgaris from the stools and was also effective in cases of gastroenteritis where no pathogenic organisms were found. Streptomycin by mouth shortened the course of gastroenteritis to a considerable extent, the usual time of discharge from hospital being nine to fourteen days after the start of treatment. The early administration of streptomycin by mouth in gastroenteritis may make it possible to omit a period of starvation and to give generous feeds throughout the illness. It is not expected that all types of gastroenteritis of unknown causation or those of virus origin will respond to streptomycin given by mouth. There is danger that pathogens remote from the intestine may be rendered streptomycin-resistant by the small amount of streptomycin that enters the blood stream.

**Human Tuberculosis Due to Avian Bacilli.**—According to Finlayson tuberculosis in human beings caused by the avian bacillus is rare. The case reported here was the first one observed in New Zealand. This avian bacillus was encountered in the course of routine typing of acid-fast bacilli isolated from human cases of extrapulmonary tuberculosis. The patient was a 14 year old girl with a swelling in the neck below the angle of the jaw. At operation an enlarged lymph node was removed. The organism was isolated on yolk-enriched egg medium. The organism emulsifies readily in water and saline solution. In this respect it is like avian and unlike human or bovine bacilli. Colonies of the bacillus show glycerophilism, and on mediums containing glycerol are pigmented (ochre), thus conforming to avian type. The organism is highly virulent for rabbits and chickens. It is capable of producing an active tuberculin that gave positive results with chickens which had been infected with an authentic strain of Mycobacterium avium.

*Tropical Eosinophilia and Loeffler's Syndrome. Bertha Bouroncle.—p. 283.

**Loeffler's Syndrome.**—Bouroncle reports a clinical, hematologic and roentgenologic study of 9 cases of Loeffler's syndrome. She states that tropical eosinophilia, eosinophilic leukemoid syndrome and transient eosinophilic infiltration of lung (Loeffler) are clinical symptoms of the same infection, whose agent is unknown. The disease runs an early subacute course and a late benign course. There is an early phase with anemia in all of the cases, but in some a severe hypochromic macrocytic anemia is present. Bone marrow biopsy in these cases shows eosinophilic hyperplasia of adult forms and normoblastic erythropoietic hyperplasia. Anemia appears to be due to destruction of erythrocytes by a pathologic infectious agent. Infection stimulates the bone marrow to produce an abnormal number of eosinophils, with predominance of mature forms which infiltrate several organs, especially the liver. In the stage of toxic infection results of colloidal gold, of cephalin and cholesterol tests are positive, the albumin content of the blood is diminished, that of blood globulins is increased and the albumin-globulin ratio is low. In all cases total cholesterol in the blood serum is diminished in direct relation to the increased eosinophilia, whereas both the sedimentation rate of the erythrocytes and the fibrinogen content of the blood are increased. Diagnosis of tropical eosinophilia depends on ruling out pulmonary tuberculosis, cholelithiasis and appendicitis. The clinical diagnosis should be confirmed by serial hematologic and biochemical studies of the blood and by roentgen examination of the thorax. The author employed arsenical therapy in 3 of the cases without effect. Better results were obtained by administration of a well balanced diet and lipotropic substances which stimulate hepatic function.

**Lobectomy in Bronchiectasis.**—Stutz points out that, although the first surgical removal of a pulmonary lobe was carried out by Sauerbruch in 1915, it was rarely employed in Europe until after it had been further perfected by surgeons in the United States. The decision to perform lobectomy in patients with bronchiectasis requires exact knowledge of the localization and extent of bronchiectasis. Simple roentgenography is inadequate. Tomography and visualization of the bronchial tree by means of a contrast medium are required. Bronchography should be carried out before a lobectomy is undertaken. Bronchography gives information about the elasticity. These preoperative examinations are explained on the basis of 2 case histories. The patient's general condition must also be taken into consideration in deciding on the advisability of a lobectomy. Patients who have an advanced form of bronchiectasis rarely are good subjects for lobectomy. The surgical prognosis is better the shorter the duration of the bronchiectatic process. Age is also a decisive factor, patients under 40 having the best prognosis. Lobectomy represents a decisive advance in the therapy of bronchiectasis.

**Procaine Hydrochloride Block for Thrombophlebitis.**—Anselmino and Sauer cite observations of French and American investigators on the use of the procaine hydrochloride block in the treatment of thrombophlebitis and comment on the American concept of differentiation between thrombophlebitis and phlebothrombosis. They have performed sympathetic block in 68 patients with thrombophlebitis. In 46 of these patients, the block resulted either in complete cure or in such improvement that the patients were nearly free from complaints. In 15 patients with old thrombosis complicated by crural ulcer sympathetic block was followed by clearing of the wound surfaces and by the appearance of fresh granulations, and in 8 of the cases by subsequent rapid healing of the ulcers. Stasis and edema after thrombosis are not the result of mechanical closure of the vessel, but are due to ischemia resulting from spastic closure of the arterioles and of the venous collaterals. This spastic closure is elicited by means of a vasoconstrictor reflex originating in the wall of the diseased vessel and passing through the sympathetic trunk. Blockage of the lumbar sympathetic, as first suggested by Leriche, constitutes a decided advance in the treatment of thrombophlebitis, since it usually permanently interrupts the pathologic reflex.

*Two Cases of Tuberculous Meningitis. O. A. Driessen.—p. 211.
Streptomycin in Tuberculous Meningitis. A. G. Schoo.—p. 215.
*Eleven Cases of Tuberculous Meningitis Treated with Streptomycin. E. Gorter.—p. 217.
*Outcome of Tuberculous Meningitis Treated with Streptomycin in Children Clinic in 1947: 3 Cases. J. van Lookeren Campagne.—p. 237.
*Three Cases of Tuberculous Meningitis Treated with Streptomycin. Tj. Halbertsma.—p. 244.

**Two Cases of Tuberculous Meningitis.**—The first of the 2 cases of tuberculous meningitis presented by Driessen concerned a boy, aged 7. Treatment with streptomycin resulted in improvement for one month, but then the boy died. The second patient was a 10 year old girl, who presented all characteristic signs of tuberculous meningitis. She also showed some improvement in response to streptomycin treatment, but she died three months later.

**Streptomycin in Tuberculous Meningitis.**—Gorter reviews observations on 11 patients who were treated with streptomycin for tuberculous meningitis. The results were bad in the children under 2 years of age in that 4 of 5 died. Of 3 children, 2 of whom were 2 and one 2½ years of age, 1 died, another had a relapse after five months of treatment and the third has recovered but is deaf. In the children over 4 years of age, the results were good; all 3 of these children have recovered, but 1 is completely deaf. The streptomycin was administered by intrathecal injections, which were continued for five weeks to two months. This was combined with daily intramuscular injections, which were continued for at least six months. All except 1 of the children were treated from the onset of the disease.

**Outcome of Tuberculous Meningitis.**—Two of the 3 patients with tuberculous meningitis treated with streptomycin by van Lookeren Campagne survive.

**Three Cases of Tuberculous Meningitis.**—All of the 3 cases of tuberculous meningitis reviewed by Halbertsma were fatal despite treatment with streptomycin.

**Therapy for Oral Discharge of Ascarides.**—Schubert says that although ascarides are usually inactive, at the time of their sexual maturation and during treatment with anthelmintics they ball together or commence to migrate. If they wander in the oral direction, they may, by their efforts to penetrate into small openings, cause serious complications such as appendicitis, pancreatitis, cholangitis or gastroduodenal difficulties. They have been known to emerge from the mouth. This oral elimination has been observed more frequently in recent times, when infestation with ascarides has enormously increased. The examination of 700 children of school age in Tübingen revealed 33.8 per cent of infestation among those less than 10 years old and 25 per cent among those up to 20 years of age. Adults who cultivated small gardens had even higher infestation rates. In a rural hospital in the region of Hannover most of the patients who were subjected to gastrointestinal operations had ascarides, and nearly three fourths of these vomited ascarides. It has been found that anacidity or subacidity usually exists in the gastric juice of patients who eliminate ascarides by mouth and treatment with hydrochloric acid counteracts the oral elimination. If treatment with anthelmintics is preceded by the administration of hydrochloric acid, elimination of the worms will be by the natural anal route.

Vomiting Caused by Esophago-Gastric Anomalies in Nurslings. M. Nicod. —p. 745.
*Treatment of Scarlet Fever by Penicillin. V. Vulliet-Baumann.—p. 755.
Treatment of Alimentary Anemia with Liver-Stomach Preparation. C. Valko.—p. 757.

**Penicillin in Scarlet Fever.**—Vulliet-Baumann says that at his isolation department penicillin treatment for scarlet fever was begun in March 1948 and since then 35 children and 2 adults have been treated. A penicillin preparation with prolonged action, a so-called depot penicillin, was administered by deep intramuscular injections. Without regard to age, 100,000 units of penicillin was given on arrival and this dose was repeated once every twenty-four hours during the following three days. The authors were favorably impressed by the results of treatment with penicillin. Its use favorably influences the initial angina and prevents the development of complications during convalescence. The early disappearance of the streptococci permits a reduction of the isolation period, which formerly was set by the cantonal health department at forty-two days. They now have ruled that the period of isolation for scarlet fever patients be governed by the same rules as that in force for diphtheria patients; that is, patients can be discharged from isolation after three negative smears have been obtained at intervals of several days. Although in the city of Geneva patients are freed from isolation as early as the tenth day, at the author's hospital in Lausanne patients are usually kept isolated for twenty-three days, because complications are feared during early convalescence. The possibility of a considerable reduction in the period of isolation is welcomed; it greatly reduces the expenses of hospitalization.

Danger of Infection and Agriculture. O. Cuendet.—p. 770.
Bellergal in Patients with Pulmonary Tuberculosis Associated with Neurovegetative Disturbances. K. Beyrer.—p. 772.

**Prognosis of Ulcer.**—According to Beust, head physician for the Swiss Federal Railroads, not less than 908 of thousands of employees who left the railroad service during the past twenty years were patients with ulcers, and that in spite of careful preemployment examinations. Statistics on these 908 cases justify the view that an increased morbidity and a premature invalidity may be expected not only in persons who were not operated on for their ulcers of the stomach and the duodenum but also in those operated on. There were recurrences in 50 per cent of the persons with ulcer. The first diagnosis of ulcer may frequently be preceded by loss of working days because of disturbances associated with the condition. Recurrences are observed in one quarter of those operated on, and other disturbances resulting from the ulcer occur in one third after the surgical intervention. As a rule, patients with ulcer, whether or not they were operated on, must be pensioned or will die several years earlier than the average of the total personnel. This statement gains in importance when one remembers that usually ulcers are observed only in persons of advanced age, while the average age at which persons are pensioned or die may be charged with diseases and accidents which are responsible for the discharge of younger persons and consequently are exerting great influence on the average age of discharge. The first relapse may occur after several years, and that applies to persons operated on as well as to those not operated on; a period of several years without recurrence should never be considered a permanent cure. The risk of morbidity and invalidity of persons with ulcer is considerably greater than that of the average of the personnel in the railroad service. Consequently the employment and insurance of persons with ulcer is not justified even though they have enjoyed good health and working capacity for several years.

*Method for Exploring Separately the Function of Glomeruli and Tubules of Kidney. J. Hamburger, A. Ryckewaert, M. Duizend and Miss N. Argant.—p. 721.

Duodenitis of $D_2$ and Problems Roused by It. L. Pavel and Paunesco-Podeanu.—p. 722.

**New Renal Function Test.**—Hamburger and his co-workers injected intravenously 10 Gm. of mannitol into normal persons and into patients with various nephropathies. To both groups 6 Gm. of para-aminohippuric acid was administered simultaneously by mouth. Thirty minutes later the concentration of the two substances in the plasma and the urine was measured in the course of two successive periods of twenty minutes. The respective clearances of the two substances were determined by the ratio between the delivery into the urine in milligrams per minute and by the concentration of the substances in the plasma in milligrams per cubic centimeter. Results showed that in normal persons the clearance of mannitol varies on an average between 120 and 130 cc.; it expresses the intensity of the glomerular filtration. The clearance of the para-aminohippuric acid exceeds 400 cc. provided that the ratio of this substance in the plasma does not exceed 10 mg. per liter; such clearance corresponds to the elimination by the kidney of all of the para-aminohippuric acid which reaches the organ. This clearance depends at the same time on the excretory power of the renal tubules and on the blood flow through the kidneys. Clearances of mannitol less than 100 cc. and clearances of para-aminohippuric acid less than 400 cc. are considered pathologic. The results obtained in the group of patients with diseases of the kidney showed that the new test is more reliable and precise than the classic procedures. It electively demonstrates an alteration of the glomeruli in the initial stage of glomerulonephritis. In arterial hypertension a morbid condition of the kidney may be disclosed very early.

**Hypervitaminosis A.**—Mouriquand cites experimental observations, some of them made as early as 1922, which suggest that administration of vitamin A may have harmful effects, if it is given in excessive doses and particularly over long periods. The danger is especially great in the absence of a properly balanced diet. Whereas rats on a well balanced diet tolerated rather large doses of cod liver oil over prolonged periods without showing signs of osseous dystrophy, animals on deficient diets exhibited after the same doses of vitamin A spontaneous fractures and generalized osseous fragility. Later investigators found that large doses of vitamin A, but not carotene (provitamin A), also produce signs of hypervitaminosis in the osseous system. Men who had eaten livers of polar bears and sea bears, which contain millions of units of vitamin A per pound, showed signs of intoxication in the form of excitation, extreme irritability, vertigo, headaches, vomiting and somnolence. Vertigo and other signs of intoxication were also observed in a man who had taken daily 6,000,000 units of vitamin A for five successive days. These symptoms subsided ten days after this medication was stopped. Other observers reported severe headaches, loss of weight and appetite, falling of hair and enlargement of liver and spleen after administration of excessive doses of vitamin A. The author hopes that the same mistake will not be made with vitamin A as with vitamin D.

Increased Familial Occurrence of Atrophy of Optic Nerve in Pelger's Nuclear Anomaly. T. Wegmann.—p. 996.

**Rutin Treatment in Osler's Disease.**—According to Markoff, Rendu-Osler-Weber's disease is characterized by Osler's triad of telangiectasia, hemorrhagic tendency with increased capillary fragility and heredity. The treatment of Osler's disease has been largely symptomatic, since a remedy that would counteract the capillary fragility has not been available, although local hemostatics and systemic measures such as iron preparations, vitamin C, vitamin K, calcium and blood transfusions have been employed. The introduction of rutin therapy seems to make possible a more effective attack on hereditary hemorrhagic telangiectasia. The author describes the chemical composition, structural formula and pharmacologic action of this flavone glucoside, its dosage and indications. On the basis of his own observations, particularly on a woman, aged 56, with a severe form of hereditary hemorrhagic telangiectasia, he describes the favorable effects that can be obtained with rutin. Six months of observation on this woman convinced him that treatment with rutin must be continuous, because intermittent treatment does not prevent recurrences. The average daily dose required by this patient was 150 mg. divided in three doses. If simultaneous administration of sulfonamide preparations is necessary, then the daily dose must be increased to 450 mg.

Total Globular Volume and Total Circulating Proteins. R. Cachera and M. Lamotte.—p. 2531.

*Place of Rubeola and of Other Infectious or Toxic Factors Occurring in Course of Pregnancy, in the Genesis of Congenital Malformations and Dystrophias. G. Lefebvre and J. Merlen.—p. 2541.

**Genesis of Congenital Malformations and Dystrophias.**—Lefebvre and Merlen studied 2,247 pediatric records in which all the peculiarities and pathologic incidents which were observed during pregnancy had been listed. The pregnancy was normal in 2,153 of these cases; in 2,121 of them the children were normal, while 32 children presented malformations or dystrophies of various type. A pathologic episode was observed in 34 pregnancies; in 14 it occurred after the third month and did not entail any fetal changes, not even in a case of poliomyelitis which occurred in the fourth month of pregnancy. Malformations or dystrophies were manifest in 20 children whose mothers experienced an incident early in pregnancy, i. e., during the first or second month. Four children had cataract, 6 had cardiac malformations, 6 were delayed in their development and had microcephaly; there were 2 instances of mongolism, 1 of palatine fissure and 1 of syndactyly. The pathologic conditions which caused these anomalies were 1 instance of rubeola inducing cataract, 4 of grip, 3 of therapeutic shock in course of infections, 2 of septicemia, 1 of mumps and 1 of scarlet fever. It appears that besides rubeola, which in France has been associated infrequently with pregnancy during the last years, numerous infections or toxic factors occurring early in pregnancy are capable of causing changes in the embryo. Certain other factors may occasionally be responsible: pregnancies occurring after a long period of sterility, pregnancies after treatment with progesterone, pregnancies of women with fibromatous uterus and maternal excessive formation of estrogens. The part played by hereditary syphilis is probably not negligible, although it may be less important than formerly believed.

# Book Notices

**Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1947, with the Comments That Have Appeared in the Journal.** Cloth. Price, $1.50. Pp. 126. American Medical Association, 535 N. Dearborn St., Chicago 10, 1948.

This volume contains several reports of rejection, the forthright and vigorous language of which reveals the Council on Pharmacy and Chemistry in its capacity of champion for honesty, decency and rationality in medicine. The concise and fearless exposure of the several preparations dealt with in the report "Drugs for Obesity" recalls the effectiveness of the early articles in "Propaganda for Reform" which, under the direction of Dr. Arthur Cramp, castigated the quackeries of those days. The reports on pyogen,® "containing ineffective dilutions of well known anti-infective agents," on ointments containing estrogens, promoted for use in cosmetics, and allergasol,® an ingeniously promoted preparation of epinephrine, are equally effective and emphasize that there is still a job to be done in protecting physicians and the public.

Two of the reports deal with the work of the Council's Therapeutic Trials Committee, one giving basic information on the Committee's work of encouraging and supporting research and investigation, the other outlining the status of the Committee's project for investigating the use of estrogens and androgens in mammary cancer.

The report and outline on streptomycin contain detailed and up-to-date information for the physician on the use of this drug. Other reports of similar nature are concerned with tetrathionate therapy in thromboangiitis obliterans, methionine in liver injury, gold therapy in arthritis and toxic reactions caused by antigens. The "Report on the Incidence of Homologous Serum Jaundice Following the Use of Surplus Dried Plasma" represents an inspiring example of cooperation between the Council and the American National Red Cross.

All these reports have appeared in THE JOURNAL. This volume offers them in collected form, together with other informative material, for the use of physicians and all those interested in the progress of rational therapeutics.

**The Clinical Management of Varicose Veins.** By David Woolfolk Barrow, M.D. With a foreword by Arthur W. Allen, M.D. Cloth, Price, $5. Pp. 155, with 58 illustrations. Paul B. Hoeber, Inc., Medical Book Department of Harper & Brothers, 49 E. 33rd St., New York 16, 1948.

Varicose veins are a public health problem. Weeks and months of disability, inability to work and loss of earning power result from neglect or poor treatment of this disorder. The present monograph fills a real need, since it offers an up-to-date guide to the management of varicose veins and their complications. The illustrations and especially their size are noteworthy. The source of these illustrations is not always obvious and, while obtainable in the text or bibliography, it should be marked in the legend. Recent advances in treating some of the resistant phlebitic ulcerations and indurations by a combination of lumbar sympathectomy, division of the superficial femoral vein and stripping of the long and short saphenous veins are described by Dr. Robert Linton. The relative merit of these procedures still awaits further study and trial.

The bibliography is well selected and representative of a progressive trend of thought. The treatise is highly recommended for the general practitioner, since the merits and limitations of customary procedures are concisely outlined. For the surgeon there is much food for thought, much stimulus for further progress.

**Diseases of the Adrenals.** By Louis J. Soffer, M.D., Associate Attending Physician, the Mount Sinai Hospital, New York. Second edition. Fabrikoid. Price, $6.50. Pp. 320, with 48 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

In the present edition, this comprehensive and authoritative monograph has been brought up to date. There have been considerable additions to the knowledge of the adrenal glands since the first edition of the book, in 1946. However, for those who already have it, the previous edition is by no means obsolete.

Those who are not familiar with this monograph are missing a useful reference work. The completeness of the treatment of the subject matter is indicated by the chapter headings: The Anatomy, Morphological Structure, and Embryology of the Adrenals; Chemical and Mechanical Techniques Important in the Diagnosis of Adrenal Cortical Disease; Physiology of the Adrenals; Physiology of the Adrenal Cortex (Continued); Addison's Disease; The Treatment of Addison's Disease; Adrenogenital Syndrome; Blood Electrolyte and Hormonal Studies; Sympathogoniomas, Neuroblastomas, and Ganglioneuromas of the Adrenal, and Pheochromocytoma and Paraganglioma of the Adrenal. The volume deserves a place in the library of the general practitioner as well as of the internist or endocrinologist.

To the reviewer, the chapter on the adrenogenital syndrome is not as satisfactory as the chapters on Addison's disease. In his opinion, the presentation, in parallel fashion, of all the variations in the clinical picture caused by the hypersecretion of different combinations of the adrenal cortical steroids is confusing. It would make for a much clearer exposition to treat hyperadrenalcorticalism as a spectrum, with the adrenogenital syndrome at one end and Cushing's syndrome at the other, and with various mixtures of the two pictures in between.

**The Surgery of Abdominal Hernia.** By George B. Mair, M.D., F.R.F. P.S.G., F.R.C.S.E., Surgeon, Law Junction Hospital, Lanarkshire, England. Cloth. Price, $7. Pp. 408, with 138 illustrations. Williams & Wilkins Co., Mount Royal & Guilford Aves, Baltimore 2, 1948.

At this stage of our development in surgery, the recurrence rate in hernia is too high. It varies from 5 to 25 per cent and may be due to faulty technic, to factors attributable to the patient or to the failure to comprehend the fundamental causes underlying the development of hernia.

In this monograph an attempt is made to explain and evaluate these points. The problems of the anatomy of the relevant areas of the abdominal wall are fully considered, and operative treatment is suggested based on an appreciation of the function of each significant structure and the causation of the particular hernia.

All the anatomic varietes of hernia (inguinal, femoral, umbilical, epigastric, diaphragmatic), even such rare ones as sciatic, obturator and lumbar, are considered. The greater portion of the book, however, is devoted to inguinal hernia. Particular attention is given to the various surgical procedures used for the repair of hernia. The recently suggested operation using whole thickness skin grafts is described—its rationale, the histologic changes which follow the use of skin implants, advantages and disadvantages and the results are discussed. The author is rather favorably inclined to this form of treatment.

The book is well written in simple language. It is well illustrated and may be recommended to those interested in the subject, beginners as well as mature surgeons.

• **Surgical Pathology.** By Peter A. Herbut, M.D., Professor of Pathology, Jefferson Medical College, Philadelphia. Cloth. Price, $12. Pp. 710, with 410 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

This text on surgical pathology is the first edition written by Dr. Herbut in an attempt to provide for the use of busy surgical pathologists, surgeons and medical students the basic information necessary for the diagnosis and intelligent management of diseases with surgical implications.

Pathology has been treated from a regional point of view, and in each region the author has provided the pertinent background of embryology, gross and microscopic anatomy based on L. B. Arey's "Developmental Anatomy," W. H. Levine's "Gray's Anatomy" and A. Maximow and W. Bloom's "Textbook of Histology." On this background the author has presented his material clearly and concisely, minimizing controversial discussion although citing fundamental and new references for those who would delve deeper into the subject. The style is smooth and lucid, vague terms as well as terms of limited or unnecessarily technical usage having been avoided. The illustrations of gross and microscopic material are profuse, well chosen and well reproduced. The practice of introducing illustrations of normal tissue for companion purposes is commendable. The value of the pathologic material presented has been enhanced by the author's brief discussions of significant facts concerned with the etiology, diagnosis, differential diagnosis, treatment and prognosis of each disease.

years, and that applies to persons operated on as well as to those not operated on; a period of several years without recurrence should never be considered a permanent cure. The risk of morbidity and invalidity of persons with ulcer is considerably greater than that of the average of the personnel in the railroad service. Consequently the employment and insurance of persons with ulcer is not justified even though they have enjoyed good health and working capacity for several years.

*Method for Exploring Separately the Function of Glomeruli and Tubules of Kidney. J. Hamburger, A. Ryckewaert, M. Duizend and Miss N. Argant.—p. 721.
Duodenitis of $D_2$ and Problems Roused by It. L. Pavel and Paunescu Podeanu.—p. 722.

**New Renal Function Test.**—Hamburger and his co-workers injected intravenously 10 Gm. of mannitol into normal persons and into patients with various nephropathies. To both groups 6 Gm. of para-aminohippuric acid was administered simultaneously by mouth. Thirty minutes later the concentration of the two substances in the plasma and the urine was measured in the course of two successive periods of twenty minutes. The respective clearances of the two substances were determined by the ratio between the delivery into the urine in milligrams per minute and by the concentration of the substances in the plasma in milligrams per cubic centimeter. Results showed that in normal persons the clearance of mannitol varies on an average between 120 and 130 cc.; it expresses the intensity of the glomerular filtration. The clearance of the para-aminohippuric acid exceeds 400 cc. provided that the ratio of this substance in the plasma does not exceed 10 mg. per liter; such clearance corresponds to the elimination by the kidney of all of the para-aminohippuric acid which reaches the organ. This clearance depends at the same time on the excretory power of the renal tubules and on the blood flow through the kidneys. Clearances of mannitol less than 100 cc. and clearances of para-aminohippuric acid less than 400 cc. are considered pathologic. The results obtained in the group of patients with diseases of the kidney showed that the new test is more reliable and precise than the classic procedures. It electively demonstrates an alteration of the glomeruli in the initial stage of glomerulonephritis. In arterial hypertension a morbid condition of the kidney may be disclosed very early.

All these reports have appeared in THE JOURNAL. This volume offers them in collected form, together with other informative material, for the use of physicians and all those interested in the progress of rational therapeutics.

**The Clinical Management of Varicose Veins.** By David Woolfolk Barrow, M.D. With a foreword by Arthur W. Allen, M.D. Cloth, Price, $5. Pp. 155, with 58 illustrations. Paul B. Hoeber, Inc., Medical Book Department of Harper & Brothers, 49 E. 33rd St., New York 16, 1948.

Varicose veins are a public health problem. Weeks and months of disability, inability to work and loss of earning power result from neglect or poor treatment of this disorder. The present monograph fills a real need, since it offers an up-to-date guide to the management of varicose veins and their complications. The illustrations and especially their size are noteworthy. The source of these illustrations is not always obvious and, while obtainable in the text or bibliography, it should be marked in the legend. Recent advances in treating some of the resistant phlebitic ulcerations and indurations by a combination of lumbar sympathectomy, division of the superficial femoral vein and stripping of the long and short-saphenous veins are described by Dr. Robert Linton. The relative merit of these procedures still awaits further study and trial.

The bibliography is well selected and representative of a progressive trend of thought. The treatise is highly recommended for the general practitioner, since the merits and limitations of customary procedures are concisely outlined. For the surgeon there is much food for thought, much stimulus for further progress.

**Diseases of the Adrenals.** By Louis J. Soffer, M.D., Associate Attending Physician, the Mount Sinai Hospital, New York. Second edition. Fabrikoid. Price, $6.50. Pp. 320, with 48 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

In the present edition, this comprehensive and authoritative monograph has been brought up to date. There have been considerable additions to the knowledge of the adrenal glands since the first edition of the book, in 1946. However, for those who already have it, the previous edition is by no means obsolete.

Those who are not familiar with this monograph are missing a useful reference work. The completeness of the treatment of the subject matter is indicated by the chapter headings: The Anatomy, Morphological Structure, and Embryology of the Adrenals; Chemical and Mechanical Techniques Important in the Diagnosis of Adrenal Cortical Disease; Physiology of the Adrenals; Physiology of the Adrenal Cortex (Continued); Addison's Disease; The Treatment of Addison's Disease; Adrenogenital Syndrome; Blood Electrolyte and Hormonal Studies; Sympathogoniomas, Neuroblastomas, and Ganglioneuromas of the Adrenal, and Pheochromocytoma and Paraganglioma of the Adrenal. The volume deserves a place in the library of the general practitioner as well as of the internist or endocrinologist.

To the reviewer, the chapter on the adrenogenital syndrome is not as satisfactory as the chapters on Addison's disease. In his opinion, the presentation, in parallel fashion, of all the variations in the clinical picture caused by the hypersecretion of different combinations of the adrenal cortical steroids is confusing. It would make for a much clearer exposition to treat hyperadrenalcorticalism as a spectrum, with the adrenogenital syndrome at one end and Cushing's syndrome at the other, and with various mixtures of the two pictures in between.

**The Surgery of Abdominal Hernia.** By George B. Mair, M.D., F.R.F. P.S.G., F.R.C.S.E., Surgeon, Law Junction Hospital, Lanarkshire, England. Cloth. Price, $7. Pp. 408, with 138 illustrations. Williams & Wilkins Co., Mount Royal & Guilford Aves, Baltimore 2, 1948.

At this stage of our development in surgery, the recurrence rate in hernia is too high. It varies from 5 to 25 per cent and may be due to faulty technic, to factors attributable to the patient or to the failure to comprehend the fundamental causes underlying the development of hernia.

In this monograph an attempt is made to explain and evaluate these points. The problems of the anatomy of the relevant areas of the abdominal wall are fully considered, and operative treatment is suggested based on an appreciation of the function of each significant structure and the causation of the particular hernia.

All the anatomic varietes of hernia (inguinal, femoral, umbilical, epigastric, diaphragmatic), even such rare ones as sciatic, obturator and lumbar, are considered. The greater portion of the book, however, is devoted to inguinal hernia. Particular attention is given to the various surgical procedures used for the repair of hernia. The recently suggested operation using whole thickness skin grafts is described—its rationale, the histologic changes which follow the use of skin implants, advantages and disadvantages and the results are discussed. The author is rather favorably inclined to this form of treatment.

The book is well written in simple language. It is well illustrated and may be recommended to those interested in the subject, beginners as well as mature surgeons.

• **Surgical Pathology.** By Peter A. Herbut, M.D., Professor of Pathology, Jefferson Medical College, Philadelphia. Cloth. Price, $12. Pp. 710, with 410 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

This text on surgical pathology is the first edition written by Dr. Herbut in an attempt to provide for the use of busy surgical pathologists, surgeons and medical students the basic information necessary for the diagnosis and intelligent management of diseases with surgical implications.

Pathology has been treated from a regional point of view, and in each region the author has provided the pertinent background of embryology, gross and microscopic anatomy based on L. B. Arey's "Developmental Anatomy," W. H. Levine's "Gray's Anatomy" and A. Maximow and W. Bloom's "Textbook of Histology." On this background the author has presented his material clearly and concisely, minimizing controversial discussion although citing fundamental and new references for those who would delve deeper into the subject. The style is smooth and lucid, vague terms as well as terms of limited or unnecessarily technical usage having been avoided. The illustrations of gross and microscopic material are profuse, well chosen and well reproduced. The practice of introducing illustrations of normal tissue for companion purposes is commendable. The value of the pathologic material presented has been enhanced by the author's brief discussions of significant facts concerned with the etiology, diagnosis, differential diagnosis, treatment and prognosis of each disease.

The pathology of the skin and the respiratory tract has been given much consideration. Also of special interest is the section dealing with congenital abnormalities of the heart. Excellent gross illustrations of the latter, together with presentation of the underlying altered physiology, has provided a good basis for understanding of the material for and the technic utilized in present cardiac surgery. No special sections have been devoted to the pathology of nervous or vascular systems, although pathologic conditions arising from these systems have been dealt with as encountered in each region. Particular attention has not been paid to the presence of injury, inflammation and repair, so often treated at length in many textbooks on pathology.

This book is not, nor is it intended to be, an encyclopedia. In the interests of brevity it must at times appear dogmatic where multiple interpretations are possible. It is authoritative, to the point and easily read, and can be recommended to a wide variety of readers.

**Dictionary of Genetics Including Terms Used in Cytology, Animal Breeding and Evolution.** Compiled by R. L. Knight, D.Sc., Ph.D., A.I.C.T.A., Senior Economic Geneticist, Empire Cotton Growing Corporation and Sudan Government. Volume II, Lotsya, A Biological Miscellany. Edited by Frans Verdoorn. Cloth. Price, $4.50. Pp. 183. Chronica Botanica Company, P. O. Box 151, Waltham 54, Massachusetts; Stechert-Hafner, Inc., 31 E. 10th St., New York 3, 1948.

A dictionary of terminology for reference in modern genetics is presented. Attempt is made to define and standardize genetic terminology. The author includes the older terminology in genetics, to enable the student to read and understand early literature in genetics, which contains terminology not in present day use. Included terms embrace those in common use in cytology, animal breeding and evolution. Appendixes are included of useful formulas; coefficients of expansion: $(1 + X)^n$ for values of $n$, and $2^n$ and $4^n$ for values of $n$; distributions of $X^2$; genotypes expected in backcrosses and in $F_2s$; tables of percentages in homozygotes; rates of elimination of donor genotype in backcrossing, and international rules for symbolizing genes and chromosome aberrations. An excellent bibliography is included.

This dictionary should be an excellent aid to those who are working directly in genetics and particularly for new students of the subject.

**Textbook of Anaesthetics.** By R. J. Minnitt, Director of Anaesthetics, David Lewis Northern Hospital, Liverpool, and John Gillies, M.C., M.B., Ch.B., J. Y. Simpson Lecturer in Anaesthetics, the University of Edinburgh, Edinburgh. With a Section on Regional Analgesia by L. B. Wevill, F.R.C.S., a Sub-Section on Its Application to Dentistry by Professor John Boyes, F.R.C.S., L.R.C.P., L.D.S., Nuffield Professor of Oral Medicine at the University of Durham, Durham, and a Chapter on Some Legal Aspects Contributed by J. Crossley Vaines, LL.M., Assistant Lecturer in Law, University of Liverpool, Liverpool. Seventh edition. Cloth. Price, $8. Pp. 568, with 229 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves, Baltimore 2, 1948.

The seventh edition has brought the sixth edition up to date, particularly with respect to the chapters on curare and on legal aspects in this field.

The portion on use of regional analgesia in operative dentistry and general operative procedures has been enlarged.

Most readers in the United States will be interested in the chapter on analgesia and anesthesia in obstetrics, especially the part that deals with self-administration of the gas by the patient.

The book is printed on good paper, is well illustrated and emphasizes many of the important technical points that are of great value in daily practice.

***Fortschritte der Biochemie 1938-1947.*** Von Felix Haurowitz, Dr.med., Dr.rer.nat., ord. Prof. de physiologischen Chemie, derzeit Vorstand des Institutes für Biochemie und Medizinische Chemie an der Universität Istanbul, Istanbul. Cloth. Price, 40 Swiss francs. Pp. 364, with 5 illustrations. S. Karger Ltd., 215 Fourth Avenue, New York 3; Holbeinstrasse 22, Basel, 1948.

This modest-looking yet attractive book represents an accomplishment that is unusual and should for that reason be especially welcome to any one wishing to reorient himself in the new biochemistry. It follows a series of volumes that appeared in 1925, 1931 and 1938, and is designed to summarize the progress in this field in readable form for physicians, chemists, pharmacologists and biologists. Although it covers more than 2,200 references to original work in the period from 1938 to 1947, the author manages to be at once coherent, accurate and interesting. His German is unaffected and readable, and his command of the subject matter is such that every fact presented appears in its proper relation to others. This will be appreciated by long-suffering readers of annual reviews in which item after item of abstruse information may be introduced without either historical background to justify it or even a conjunction to suggest its connections with what went before.

The following are the major divisions of the text: use of isotopes in biochemistry; distribution of the minerals; synthesis of organic from inorganic substances; carbohydrates; substances related to the polysaccharides; biochemistry of fatty acids and their derivatives; carotenoids; sterols and steroids; chemistry and metabolism of proteins; the blood pigment and its derivatives; hormone proteins; vitamins and growth-promoting substances; antibiotics and related substances; nucleic acids and their derivatives; intermolecular forces in the living substance; hydrolases; oxidation-reduction reactions; biochemical thermodynamics and kinetics; chemistry of muscular contraction and nervous conduction; immunochemistry; cytochemistry, and laboratory methods. While most topics are easily located within particular chapters, the search is facilitated by a good subject index.

The scarcity of German and French references in the bibliographies is a saddening reminder that biochemical publications in those languages fell far behind during the period covered; for that reason, an American reader looking for clues to recent European work will find little. The book is more likely to be useful to the European reader seeking to locate American data. It is therefore gratifying to report that in this respect the bibliographies, which follow each chapter, are representative and accurate. The book can be recommended without reservations to biochemists and physiologists.

***Ärztliche Rheokardiographie.*** Von Wolfgang Holzer und Kurt Polzer. Band III, Bücherei der physikalischen Medizin. Herausgegeben von Professor Dr. Wolfgang Holzer. Paper. Price, $3. Pp. 141, with 88 illustrations. Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2; imported by Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1948.

As the authors point out on page 7 the apparatus which they describe and utilize is similar to that independently presented by J. Nyboer in this country in 1940, as the Electrical Impedence Plethysmograph. After describing the principle and the details of the apparatus and procedure there is a theoretic development which goes far afield. This is followed by a typically Germanic elaborate detailing of the use of the instrument under various circumstances clinically. When the entire text is boiled down, it is found that the authors apparently have used this method almost exclusively to determine the isometric contraction period and the ejection time. The reviewer is left with a feeling that there is much ado about trivialities. The technic employed needs considerable implementation before it can be considered of value as an added tool for research or clinical analyses.

***Refraction of the Eye.*** By Alfred Cowan, M.D., Professor of Ophthalmology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Third edition. Fabrikoid. Price, $5.50. Pp. 287, with 190 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

This is the third edition of a popular short book on refraction. Its popularity is due to the short but clear descriptions, explanations and examples, as well as the adequate illustrations. It combines the essentials of physiologic optics with methods of examinations and clinical application of optics. It is a good book for students and the young clinician who may avoid pitfalls if careful study of the author's advice of what to prescribe is followed closely. The final chapter on contact lenses and telescopic spectacles is pertinent. Its continued use for the teachers and students of clinical refraction is recommended.

**Food Value Charts.** Cardboard. Price, $1, per set of twelve charts. Philadelphia Child Health Society, N. E. corner 7th & Delancey Sts., Philadelphia 6, 1948.

This set is a revision of a similar series published in 1946. They measure 10 by 12½ inches, are printed on cardboard and provide a useful medium of visual education. Values for cooked foods have been used rather than values for raw foods. These charts are attractive and useful and worthy of note by physicians or other professional persons who need such material for teaching purposes.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## CHRONIC HEADACHE

*To the Editor:*—A white woman, age 30, married and mother of three children, has suffered for a long time from periodic headaches, which are almost entirely located in the occipital region, are of extreme severity and usually accompanied with vomiting. In recent months headache has occurred almost always only at the menstrual period or just before. During the preceding ten or twelve years it has usually occurred at the menstrual period also, but in addition has frequently occurred between the periods, particularly if the patient has been subject to any emotional stress or strain. In recent months the patient's menses have become irregular, so that she can never be certain when the flow will appear. However, the headache is often the warning signal and is usually accompanied with moderate uterine cramps. Physical examination reveals a uterus within normal limits as to size, but this organ is definitely tender, as is the right tube. About three years ago the patient had a Baldy-Webster suspension for pronounced ptosis of the uterus, and the headaches were completely relieved by this operation for a period of nine or ten months. Are these headaches due entirely to pelvic disease, and, if so, is hysterectomy warranted?
M.D., Nebraska.

Answer.—Hysterectomy is not indicated in this woman, because the uterus is surely not the direct cause of the headaches. Indirectly, the uterus may be responsible for the headaches through the psyche. For example, if the patient has a morbid fear of having more children, she may wish to have the uterus removed so that there will be no possibility of a pregnancy. In such a case psychotherapy is indicated. It is not stated whether the "ptosis" of the uterus recurred when the headaches came back nine or ten months after the Baldy-Webster suspension.

It is assumed that the woman has had a thorough physical examination, which failed to reveal any cause for the headaches. The headaches may be migraine. Since they often arise or are severer a few days before the onset of the menstrual flow, two types of therapy should be tried. The first is the use of ammonium chloride, 0.6 Gm., three times a day during the fourteen days before the menstrual bleeding begins. During these fourteen days the patient must refrain from adding table salt to her food. The second recommendation is to give a 10 mg. tablet of methyl testosterone daily for the ten days before the expected onset of the menstrual flow.

## DIABETES IN PREGNANCY

*To the Editor:*—A 26 year old woman has diabetes. In 1945 the patient had diabetic coma. Control of the condition has been fair since that time. Her fasting blood sugar is now 88 mg. per hundred cubic centimeters. Blood count and urine are normal. Physical examination does not reveal other abnormalities. She is receiving a mixture of 33 units of protamine zinc and regular insulin. What is your advice concerning pregnancy in this patient?
Alan L. Hays, M.D., Odessa, Texas.

Answer.—One can speak only in generalities because of the individual variation both of diabetes and of pregnancy. The younger the age of a patient when diabetes manifests itself, the more severe the disease is likely to be. A patient who cooperates and in whom the diabetes has been and is easily controlled is more likely to have a successful pregnancy than one who is difficult to control. If the patient becomes pregnant, she should be observed carefully with special reference to control of diet to prevent undue weight gain and she should probably have salt restricted from the beginning in addition to increased protein intake. Careful checking of the diabetes is essential at frequent intervals. The diabetes should be controlled by an internist thoroughly competent in its management. Diabetic patients are more apt to have complications. They are inclined to have large babies and to have toxemias of pregnancy.

There are two schools of thought on the specific treatment of these patients. Priscilla White has performed outstanding work with hormones. She believes that they are not only helpful but essential in the treatment of the diabetic pregnant patient.

A young woman anxious to have a family should not be advised against becoming pregnant, but she should be acquainted with the fact that she may have diabetic children.

The last trimester is the most trying time, and it is during this stage that the patient should be watched for early signs of toxemia.

## PENICILLIN OINTMENT IN ATOPIC DERMATITIS

*To the Editor:*—Please comment on the use of penicillin ointment (fatty base), 500 units per gram, in the treatment of atopic dermatitis. This ointment was prescribed and exclusively used in a case of atopic dermatitis diagnosed as such and treated by a dermatologist (a certified specialist). The patient is a girl of 12 who for two years had a skin lesion just above one ankle, on the anterior surface. The lesion was at first thought to be a fungous infection. It spread locally and then appeared on face and neck and invaded the aural canals. The treatment mentioned completely cleared the condition in four to five months. Has penicillin any effect on allergies of the skin?
M.D., New York.

Answer.—All available evidence would seem to indicate that penicillin has no beneficial effect on allergic diseases except in those cases in which there is an associated infectious element due to an organism that is sensitive to penicillin. That is true also for eczema-dermatitis. It is of value only when there is secondary infection or an infectious dermatitis. Atopic eczema is a notoriously capricious disease which may enjoy spontaneous remissions from time to time, and, of course, the medication of the moment is usually credited with effecting the cure. Such a remission may have occurred in this case, or it may be that the ointment base actually had a protective and soothing effect on the dermatitis.

## KVEIM TEST

*To the Editor:*—Kindly describe the Kveim test for sarcoid.
M.D., Pennsylvania.

Answer.—The Kveim test is a cutaneous test used in the study of sarcoidosis, just as the Frei test is used in lymphogranuloma venereum.

One tenth cubic centimeter of antigen prepared from lymph nodes (or cutaneous infiltrates or tonsils) of patients with sarcoidosis is injected intracutaneously, usually on the flexor surface of the forearm. A positive reaction consists of an infiltrated area, papule, nodule or superficial necrosis with ulceration, which appears at the site of injection sometimes within two weeks, sometimes not for several months, and it may be observable for many months thereafter. In doubtful cases, a histologic examination of the papule with demonstration of a tuberculoid structure would tend to support the diagnosis of sarcoidosis. The antigenic material is not available commercially.

## BEDSIDE METHOD FOR BLOOD SUGAR

*To the Editor:*—In your journal dated Oct. 2, 1948 on page 356, in the article entitled "Insulin and Diet" by H. T. Ricketts, M.D., under abstract of discussion, Dr. E. P. Joslin of Boston speaks of a blood sugar test introduced by Mrs. Leech. Please inform me of the method used. Is it practical for daily office use?
Kerman Snyder, M.D., Philadelphia.

Answer.—The blood sugar method referred to is that of Leech and Woodford (Leech, R. S., and Woodford, N.: A Simple Bedside Method for the Estimation of Blood Sugar, *Jour. Lab. and Clin. Med.* 33:2-8 [May] 1948). According to the authors, the procedure involves a minimum of time, equipment and laboratory facilities. Only approximate results are claimed since the final color produced is compared either with a standard color chart or a series of standard tubes. In their article the authors give figures obtained by them which agree within 5 to 20 mg. of those obtained by blood sugar methods in common use. It would appear that the procedure is practical for office use and desirable particularly if laboratory and technical facilities are limited.

It is appropriate in this connection to call attention to another rapid blood sugar method which has been devised as a screening procedure. The details may be found in an article recently published (Wilkerson, H. L. C., and Heftmann, E.: Screening Method for Blood Glucose, *Jour. Lab. and Clin. Med.* 33:236-238 [Feb.] 1948).

## PREOPERATIVE SKIN MARKING

*To the Editor:*—I have noted in The Journal frequent descriptions of medicolegal cases arising from burns caused by silver nitrate used for the preoperative marking of varicose veins. Please suggest a safer solution which will leave a mark that will withstand a routine skin preparation of soap, water, alcohol, ether and "merthiolate."
Henry M. Stern, M.D., Martinsburg, W. Va.

Answer.—Two per cent aqueous solution of brilliant green has been widely employed for the marking of skin incisions. The dye is not irritating, is mildly antiseptic and shows up under iodine or "merthiolate" solutions. Extensive scrubbing with soap and water obviously produces a fading of brilliant green.

## HYALURONIDASE IN PEMPHIGUS

*To the Editor:—How is the hyaluronidase effect in pemphigus tested? What is the significance of an increased spreading rate?* M.D., Pennsylvania.

Answer.—The hyaluronidase effect in pemphigus has been measured by the ability of the patient's serum or bullous fluid to reduce the viscosity of a hyaluronic acid solution as measured in an Ostwald viscosimeter.

The hyaluronidase inhibitor effect has been measured by treating the enzyme, hyaluronidase, with the patient's serum or bullous fluid and comparing the viscosity reducing power on hyaluronic acid of treated and untreated hyaluronidase.

These measurements are also made in an Ostwald viscosimeter under standard conditions.

An increase in the spreading rate by the intradermal test indicates that the connective tissue barriers have been made weaker, presumably by hyaluronidase action.

## PRESERVATION OF TISSUE

*To the Editor:—Please supply sources of information concerning methods for the preservation of fresh soft tissue specimens in clear plastic.*

Donald W. Ross, M.D., Washington, D. C.

Answer.—Strumia and Hershey (*Science* 99:105-106, 1944) have applied ethyl methacrylate to large moist anatomic specimens to make permanent museum pieces with good results. Recently Peck and Gray (*Am. J. Clin. Path.* 18:910-912, 1948) have used butyl methacrylate for specimens that have been fixed in Kaiserling solution to preserve the color. This method is simple and the specimens have not become dehydrated or discolored in the year that the method has been in use.

## PROGNOSIS FOR CONGENITAL MALFORMATION

*To the Editor:—Patients of mine have 2 children. One was born with absence of certain extrinsic muscles of one eye. The second child was born without a right forearm. Family history of congenital defectiveness is absent. The parents have asked whether they should avoid a third pregnancy. What should be my advice?* C. H. Storey, M.D., Vallejo, Calif.

Answer.—There appears to be a greater likelihood of a baby's having some malformation at birth if its mother has given birth to other children with malformations. Murphy suggests that this hazard is twenty to twenty-five times greater in the woman who has already given birth to an abnormal child than in the population at large. However, statistical studies are inadequate.

## ATROPHY OF TESTICLE WITH VARICOCELE

*To the Editor:—What is the incidence of testicular atrophy from varicocele and following varicocelectomy?* M.D., New York.

Answer.—There may be and frequently is atrophy of the testes from a large varicocele. With small varicoceles, the testes are usually normal as far as the gross examination is concerned. Varicocelectomy, if properly done, should not produce atrophy of a testis that was previously normal. However, if the arterial blood supply is interfered with, then atrophy of the testes can occur.

## SURGERY FOLLOWING IRRADIATION

*To the Editor:—What is the optimum time for total hysterectomy following treatment of carcinoma of the cervix with 6000 mg. hours of radium?*

M.D., Virginia.

Answer.—Following the application of radium it takes three weeks for the maximum effect. Regression then takes another four to six weeks. This, therefore, is the optimum time for surgical intervention. If surgery is undertaken during the time of irradiation erythema, edema and increased vasodilation make the procedure difficult. If too much time elapses, the secondary effect of fibrosis begins and this also makes surgical removal of the uterus difficult.

## CANCER OF THE BREAST

*To the Editor:—In a 69 year old patient with a carcinoma of the breast the size of a bean and without axillary metastasis, is simple mastectomy adequate surgical treatment? Should irradiation be given postoperatively?*

Frederick Elias, M.D., Monticello, N. Y.

Answer.—Simple mastectomy is not adequate for operable mammary cancer. Complete radical operation is required. A difference of opinion exists regarding the value of prophylactic postoperative radiation. If the axillary lymph nodes [illegible] be free of carcinoma microscopically, there is an increasing tendency to omit postoperative radiotherapy.

## PROSTATIC CANCER

*To the Editor:—The patient, an American medical missionary, age 69, was operated on in January 1947 for enlarged prostate. Microscopic examination showed adenocarcinoma. He made a rapid recovery from all body pains, which were severe on left side from shoulder to ankle by taking 2.5 mg. of diethylstilbestrol daily. He left Florida in April, driving to San Francisco to make the return trip to India. He was free from pain until December 1947, playing badminton almost daily. Pain has gradually increased since, and he now requires from 40 to 50 grains (2.4 to 3 Gm.) of acetylsalicylic acid to control them partially. Roentgenograms of shoulder and hip bones show little change in carcinoma growth in the period from December 10 to June 10. He is taking 30 mg. of diethylstilbestrol daily at present. He tried up to 75 mg. daily but discontinued. Is there something better to control the pain?* Hugh H. Linn, M.D., Bowringpet, India.

Answer.—It is possible that this patient is having a recurrence or reactivation of his prostatic carcinoma. He has apparently had a maximum of estrogen therapy, and at age 69, it would seem advisable that he now have bilateral orchiectomy, which may have as spectacular effect, for a few months or even years, as the taking of estrogen had for eleven months. In some instances, however, orchiectomy following prolonged administration of estrogens does not have much beneficial effect. If orchiectomy does not relieve the pain, then the usual well tolerated sedatives in other similar types of conditions should be administered.

## POSTOPERATIVE ENDOMETRIOSIS

*To the Editor:—Please furnish information concerning the control of hot flashes and other menopausal symptoms in a woman 30 years of age who had a bilateral oophorectomy for extensive pelvic and abdominal endometriosis. We have avoided estrogenic therapy for fear of its possible effect on existing endometrial implants that were found to be too numerous to remove.* M.D., New York.

Answer.—Generally, when women have menopausal symptoms following castration for endometriosis, the symptoms are treated not with estrogens but with androgens. The simplest procedure is to have the patient take one or two 10 mg. tablets of methyl testosterone daily for two or three weeks at a time. Or the patient may be given 10 to 25 mg. of testosterone propionate hypodermically once or twice a week for three or four weeks at a time. Some women are not helped sufficiently by androgens alone. In such instances small doses of phenobarbital often help or small amounts of estrogen may be given with the androgens. For example, the patient may be given a combination of 10 mg. methyl testosterone and 0.25 mg. diethylstilbestrol at the same time.

Karnaky (*Am. J. Obst. & Gynec.* 56:146 [Nov.] 1948) advocates the deliberate use of large doses of diethylstilbestrol for the treatment of endometriosis instead of surgical treatment. He begins treatment with 5 mg. diethylstilbestrol daily and increases the dose used each week by adding 5 mg. to the daily dose for a few months. He claims good results from this treatment.

## PINWORM EGGS

*To the Editor:—What substance will kill cystic forms of the common pinworm in the rooms in which infected persons reside? We can eliminate the worms from the child, but he reinfects himself from toys, floors and walls.*

W. B. Herter, M.D., Honolulu, T. H.

Answer.—Unfortunately practical and effective methods of destroying pinworm eggs on floors, rugs and furnishings in the homes of infected persons are not known. Various cleansing agents and disinfectants, as commonly employed, are not effective for killing the eggs. In laboratory experiments, exposure to a 10 per cent solution of saponated cresol solution U. S. P. for three to five minutes destroyed the eggs. A solution of saponated cresol solution (lysol®) 1:32 in water killed the eggs in about fifteen minutes. The use of these solutions on bathtubs, toilet seats, lavatory bowls and fixtures may help in limiting the spread of infection. The facilities should not be used until they have been flushed with cold water thirty minutes after application of the disinfectant. It is obvious that the hands should be protected with rubber gloves in applying the solution. Frequent use of a vacuum cleaner on walls, furniture and floors may aid in the removal of viable ova and thus help to prevent spread of infection.

## TULAREMIA ENCEPHALITIS

*To the Editor:—In the Query and Minor Note, "Tularemia Encephalitis" (The Journal, Oct. 9, 1948, page 466), is the statement, "As far as is now known, neither streptomycin nor high voltage roentgen therapy would be of any avail against the bacillus of tularemia." Your statement, when applied to this particular patient, may be true, but streptomycin is [illegible]ment of tularemia according to all reports on the proved cases of acute disease except those exhibiting encephalitis.*

[illegible], M.D., National Institute of Health, Bethesda 14, Md.
